1 Getting started with Dymola

1.1 Introduction

This chapter will take you through some examples in order to get you started with Dymola. For detailed information about the program, you are referred to the on-line documentation and the user's manuals. The on-line documentation is available in the menu **Help > Documentation**. The tool tips and the **What's this?** features are fast and convenient ways to access information. Please see section "Help and information" on page 84 for more information.

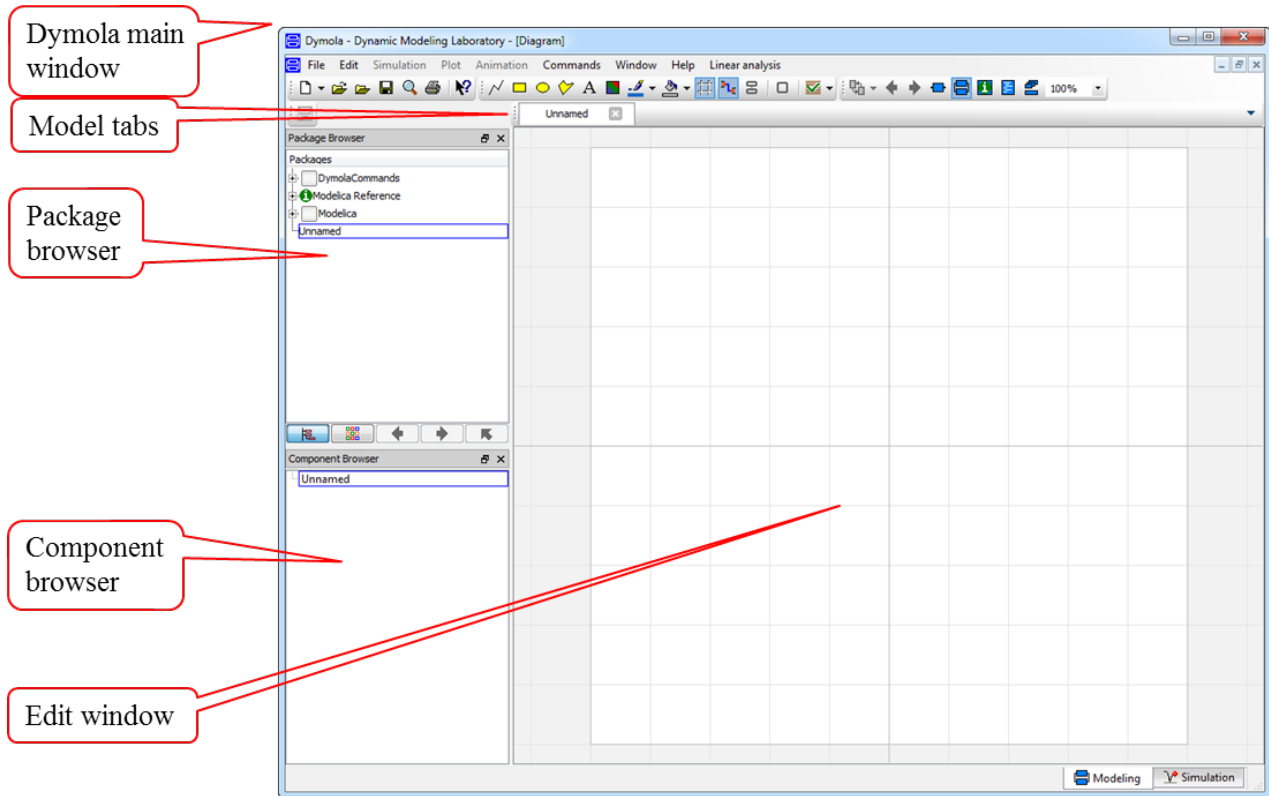

Start Dymola. The main Dymola window appears. A Dymola main window operates in one of the two modes:

- **Modeling** for finding, browsing and composing models and model components.
- **Simulation** for making experiments on the model, plotting results, and animating behavior.

Dymola starts in Modeling mode. The active mode is selected by clicking on the tabs in the bottom right corner of the Dymola window.

The operations, tool buttons available and types of sub-windows appearing depend on the mode and the user's choice. Dymola starts with a useful default configuration, but allows customizing.

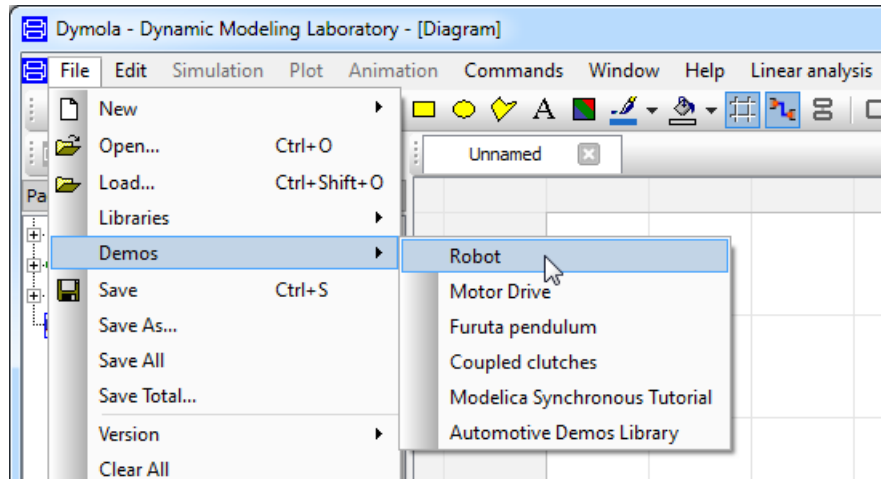

1.2 Simulating a model — industrial robot

This first example will show how to browse an existing model, simulate it, and look at the results. If you want to learn the basics first, you can skip to a smaller example in the next section 1.3 “Solving a non-linear differential equation” on page 20.

1.2.1 Investigating the robot in modeling mode

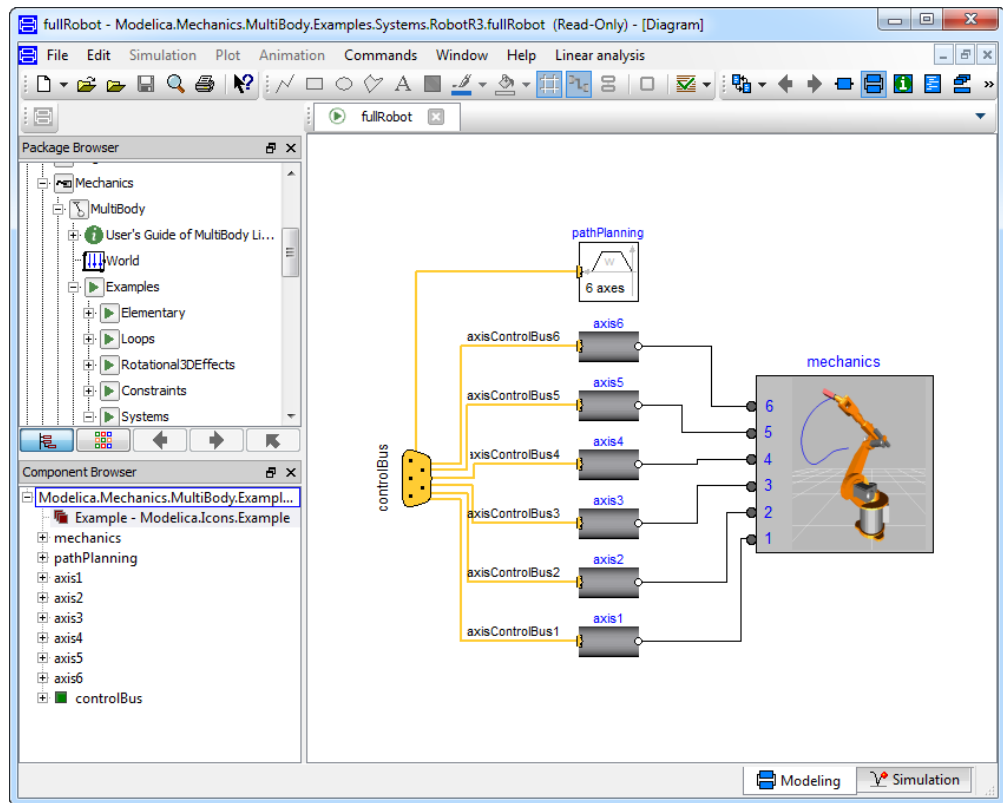

We will study a model of an industrial robot. To view the industrial robot model, use the **File > Demos** menu and select **Robot**.

Opening a demo example.

Dymola starts loading the model libraries needed for the robot model and displays it. The following will be displayed:

The robot demo.

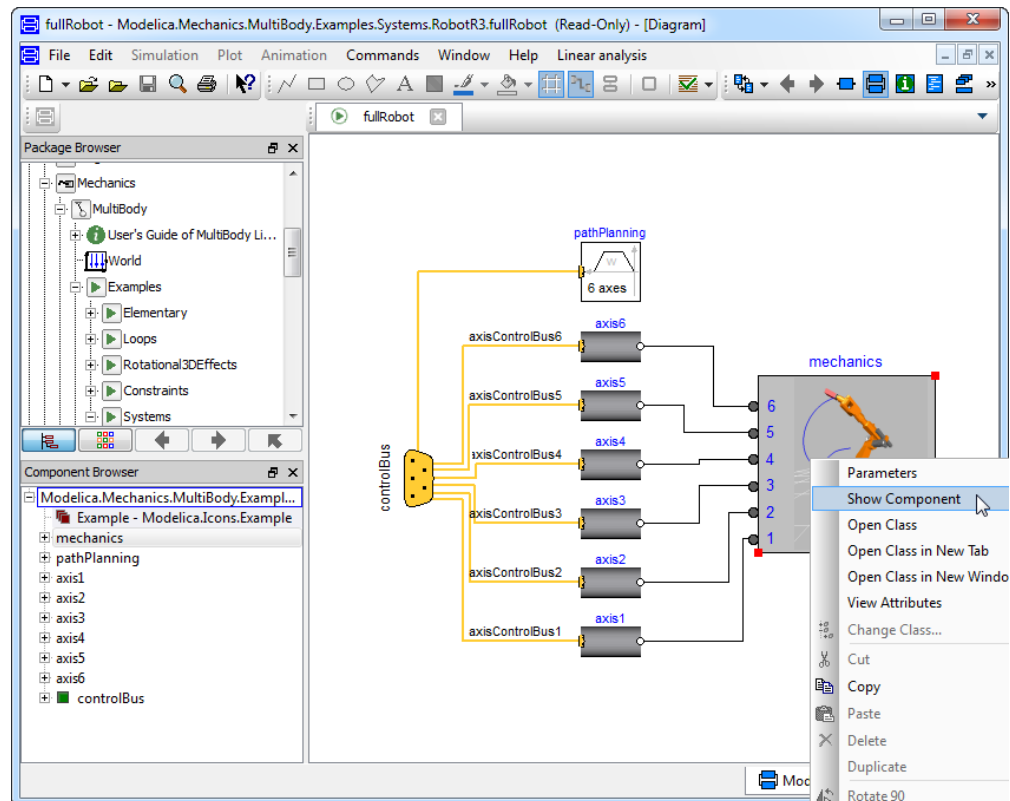

The package browser in the upper left sub-window displays the package hierarchy and it is now opened up with the robot model selected and highlighted. The model diagram in the edit window (the sub-window to the right) shows the top-level structure of the model. The model diagram has an icon for the model of the robot with connected drive lines for the joints. The reference angles to the drive lines are calculated by a path planning module giving the fastest kinematic movement under given constraints.

The edit window displays by default the model diagram (“diagram layer”) but the user can select other information (other layers) to be displayed instead, e.g. documentation or Modelica text. For more information, please see the chapter “Developing a model”.

The component browser in the lower left sub-window also shows the components of the robot experiment in a tree structured view.

To inspect the robot model, select the icon in the edit window (red handles appear, see below) and right-click (press the button to the right on the mouse). A menu pops that contains a selection of actions that can be made for the selected object (a context menu). From the context menu, select **Show Component**.

About to view the mechanical structure of the robot.

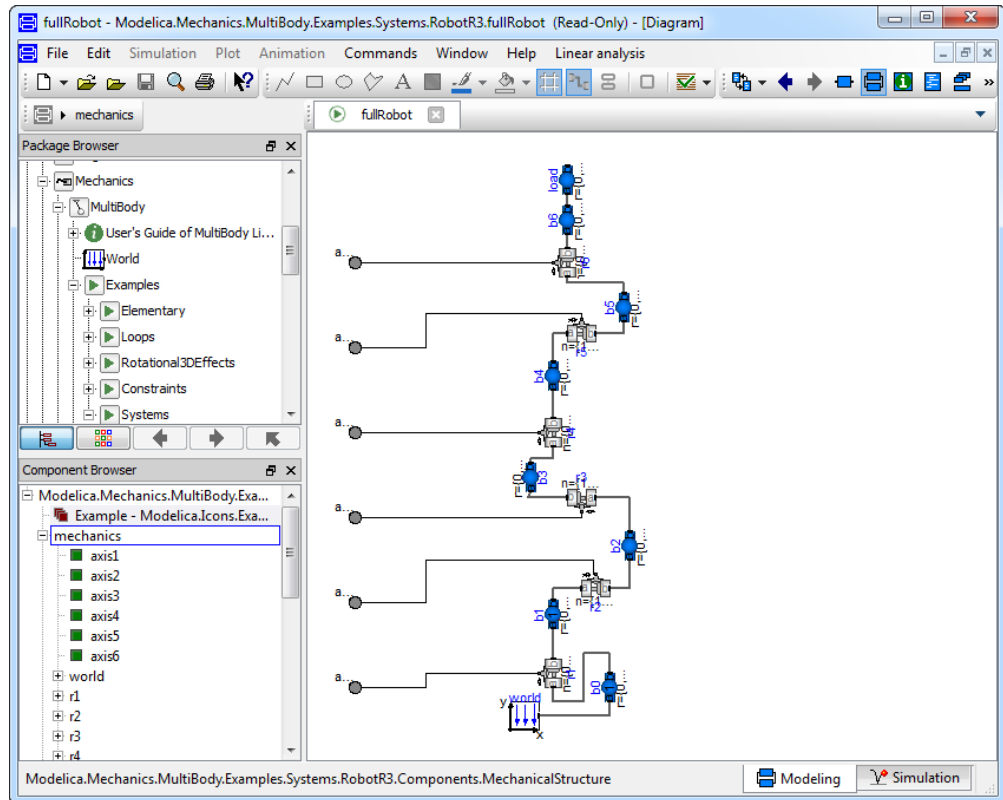

It is not necessary to select the robot component explicitly by first clicking with the left button on the mouse on it to access its menu. It is sufficient to just have the cursor on its icon in the edit window and right-click. The component browser also gives easy access to

the robot component. Just position the cursor over “mechanics” and right-click to get the context menu for “mechanics”. The component browser provides a tree representation of the component structure. The edit window showing the diagram layer and the component browser are synchronized to give a consistent view. When you select a component in the edit window, it is also highlighted in the component browser and vice versa. The diagram layer of the edit window gives the component structure of one component, while the component browser gives a more global view; useful to avoid getting lost in the hierarchical component structure.

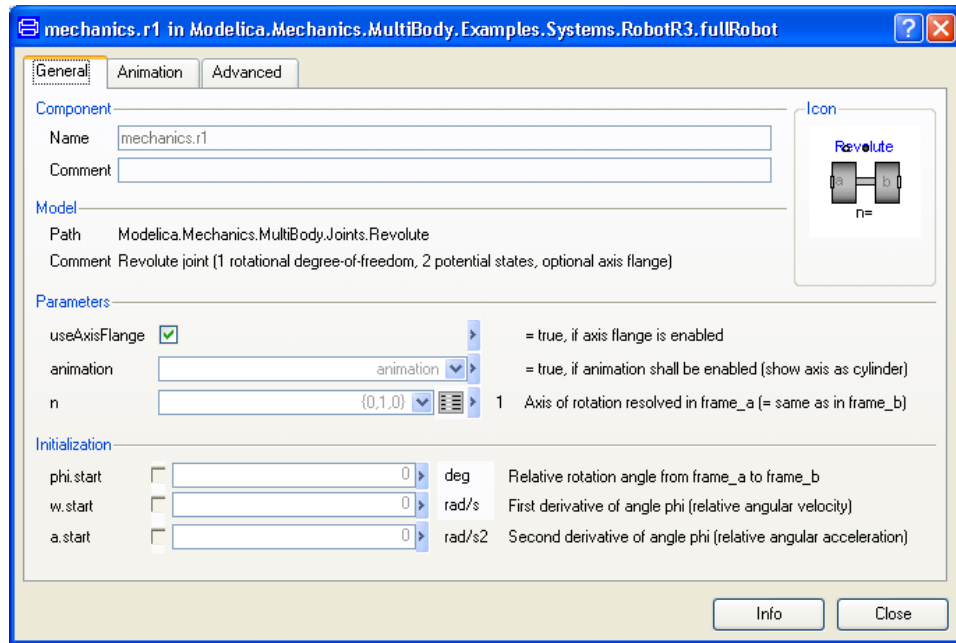

The edit window now displays the mechanical structure consisting of connected joints and masses. The component browser is opened up to also show the internals of the mechanics model component.

The mechanical structure of the robot.

Double-click on, for example, r1 at the bottom of the edit window. This is a revolute joint. The parameter dialog of that component appears. The parameter dialog can also be accessed from the right button menu. Double-clicking the left button selects the first alternative from the right button menu.

Parameter dialog.

The parameter dialog allows the user to inspect actual parameter values. In demos the parameter values are write-protected to avoid unintentional changes of the demo example – then the dialog just has a **Close** button (and an **Info** button). When the parameter values can be changed there is one **OK** button and one **Cancel** button to choose between. The values are dimmed to indicate they are not given at the top-level model, but somewhere down in the component hierarchy.

A parameter dialog may have several tabs. This dialog has the tabs: **General**, **Animation**, **Advanced** and **Add modifiers**. In a tab the parameters can be further structured into groups as shown. It is easy for a model developer to customize the parameter dialogs. (More information about customization can be found in the chapter “Developing a model”, section “Advanced model editing”, sub-section “Parameters, variables and constants”). Graphical illustrations can be included to show meaning of parameters.

If prepared for, display units can be selected in the dialog. Units that have alternatives are marked by white background (here phi.start and w.start have selectable display units). By resting the cursor over such a unit a button is displayed,

Selectable display unit.

and by clicking on that the selection can be made:

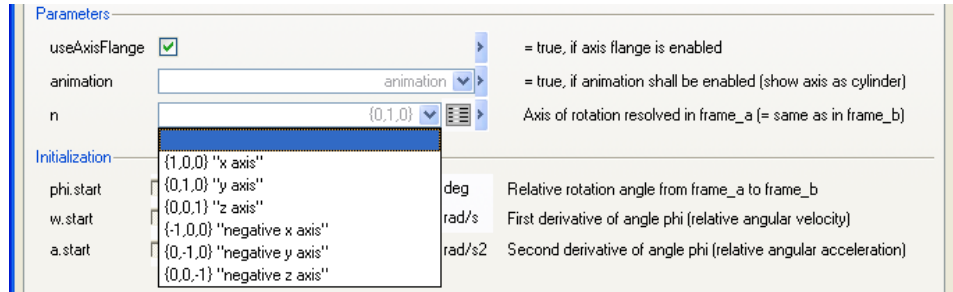

Alternatives of selectable display unit.

Next to each parameter field is a triangle, this gives you a set of choices for editing the parameters. **Edit**  gives a matrix editor/function call editor; **Edit Text** gives a larger input field, etc. An example is that for the first parameter useAxisFlange the command **Edit Text** can be used to enter an expression (that should be true in order for the axis flange to be enabled). If such an expression is entered, the checkbox will be displayed as .

Some parameters have a list of choices where you can select values instead of writing them. One example is the parameter *n*, which defines the axis of rotation. The value for this revolute joint is $\{0, 1, 0\}$, i.e. the axis of rotation is vertical.

Choices for *n*.

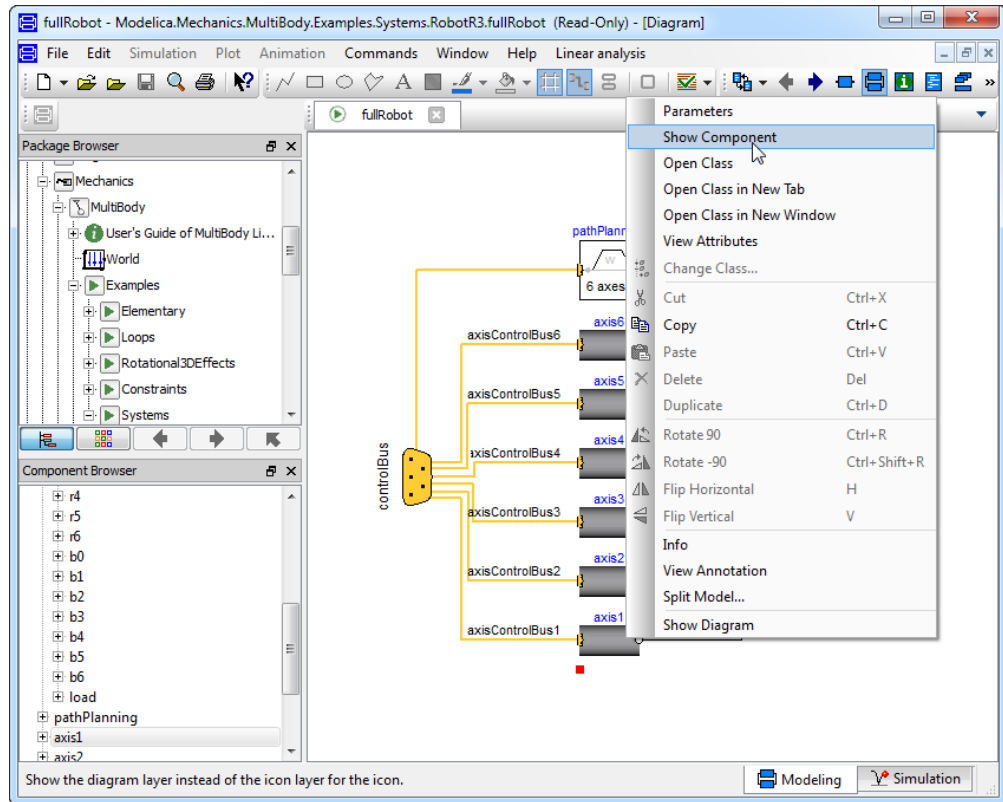

To learn more about the component, select **Info**. An information browser is opened to show the documentation of the revolute joint. Links in the document makes it easy to navigate to e.g. the description of the package containing the revolute joint. Now please close the browser and press **Close** in the parameter dialog to leave it.

(If you want to see the documentation without going via the parameter dialog, right-click on the component in the diagram and select **Info**.)

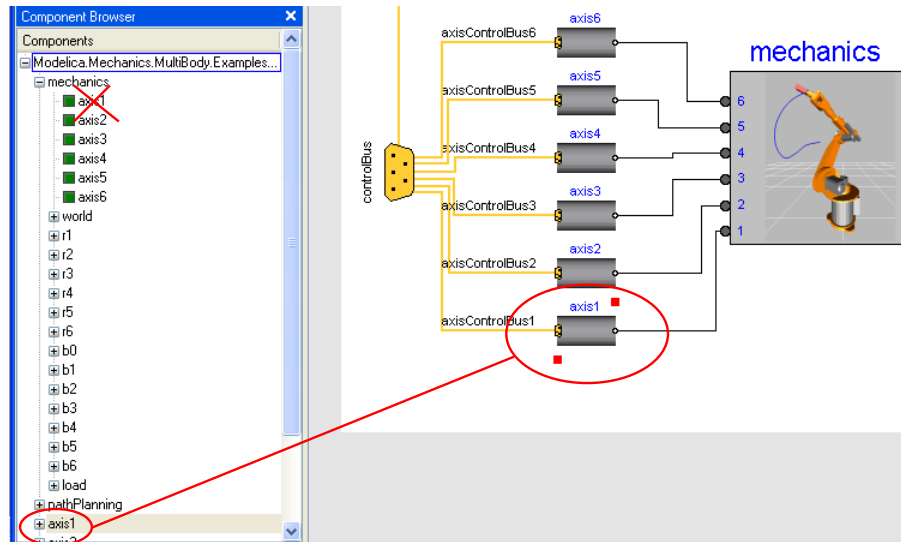

Let us now inspect the drive train model. There are several possible ways to get it displayed. Press the **Previous** button (the toolbar button with the bold left arrow) once to go to the robot model and then put the cursor on one of the axis icons and right-click. Please, note that robot.mechanics also has components axis1, ..., axis6, but those are just connectors. You must inspect for example robot.axis1 (see figure below).

Displaying the components of axis 1.

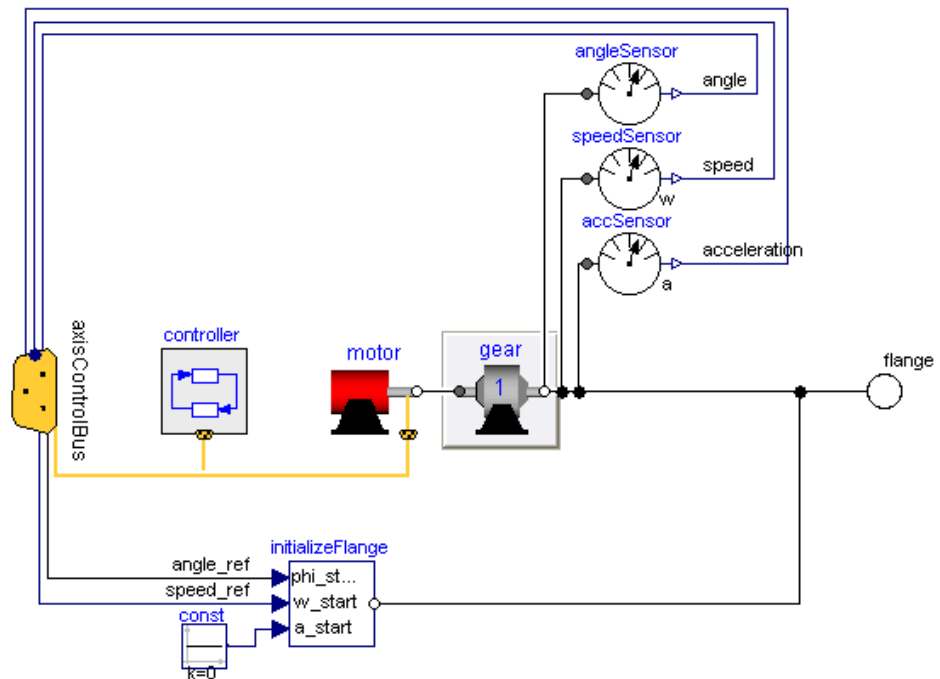

Another convenient way is to use the component browser. Put the cursor on top of the wanted component in the browser and right-click to get the context menu. Select **Show Component** as shown in the figure below. (In this case also care must be taken not to select any axes of the module mechanics. The component browser has been enlarged in the figure to illustrate this.) Since **Show Component** is the first menu option, double-clicking will yield the same result. Please recall that double-clicking on a component in the edit window pops up the parameter dialog (compare the two menus in the figure above and below!).

Displaying the components of axis 1.

Whatever method is used, the result will be the following figure in the edit window:

The robot drive train in Axis 1.

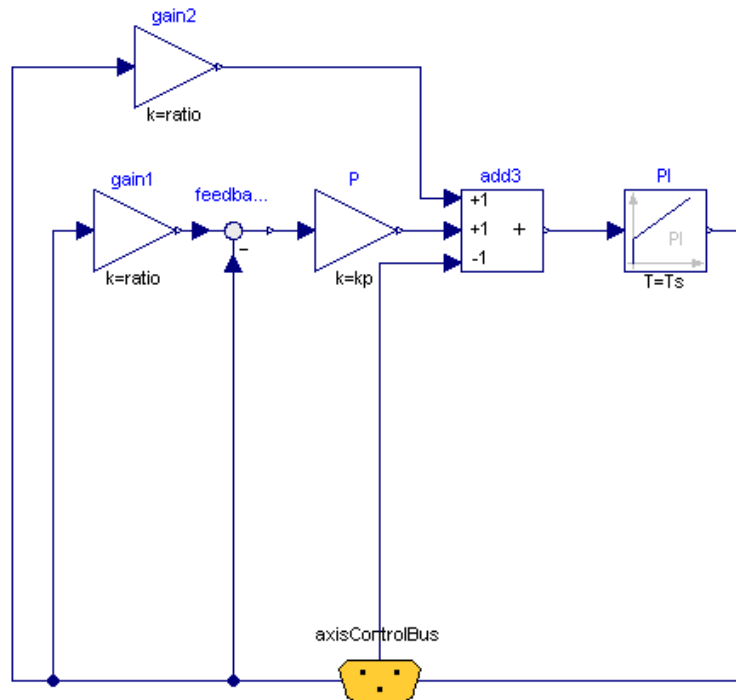

The drive train includes a controller. A data bus is used to send measurements and reference signals to the controller and control signals from the controller to the actuator. The bus for one axis has the following signals:

Name	Description
motion_ref	true, if reference motion is not in rest
angle_ref	reference angle of axis flange
angle	angle of axis flange
speed_ref	reference speed of axis flange
speed	speed of axis flange
acceleration_ref	reference acceleration of axis flange
acceleration	acceleration of axis flange
current_ref	reference current of motor
current	current of motor
motorAngle	angle of motor flange
motorSpeed	speed of motor flange

The bus from the path planning module is built as an array having 6 elements of the bus for an axis.

The figure below is displayed by selecting the controller and showing the components of it.

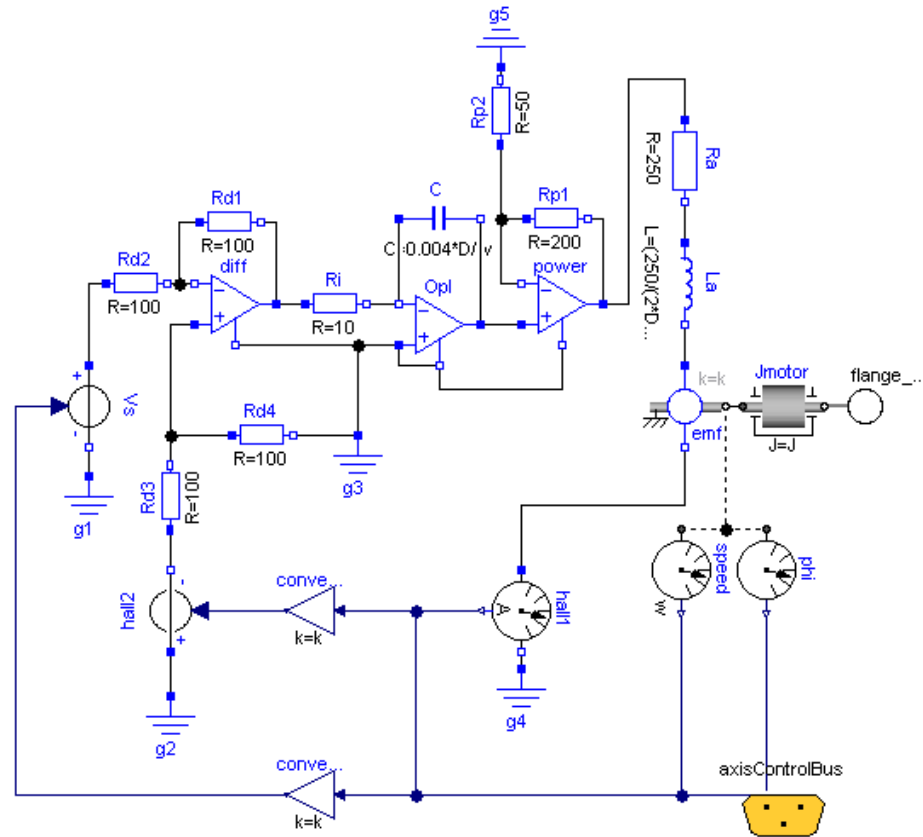

The robot controller in the robot drive train.

The controller of an axis gets references for the angular position and speed from the path planning module as well as measurements of the actual values of them. The controller outputs a reference for the current of the motor, which drives the gearbox.

The motor model consists of the electromotorical force, three operational amplifiers, resistors, inductors, and sensors for the feedback loop.

The robot motor.

View the component gear in a similar way as for the other components. It shows the gearbox and the model of friction of the bearings and elasticity of the shafts.

The robot gearbox.

1.2.2 Simulation

Let us simulate the robot model. To enter the Simulation mode, click on the tab **Simulation** at the bottom right of the main window. Please note that selecting Simulation mode is not the same as simulating the robot; it however gives the possibility doing so – the needed menus are available in this mode.

Simulating/manipulating with given values

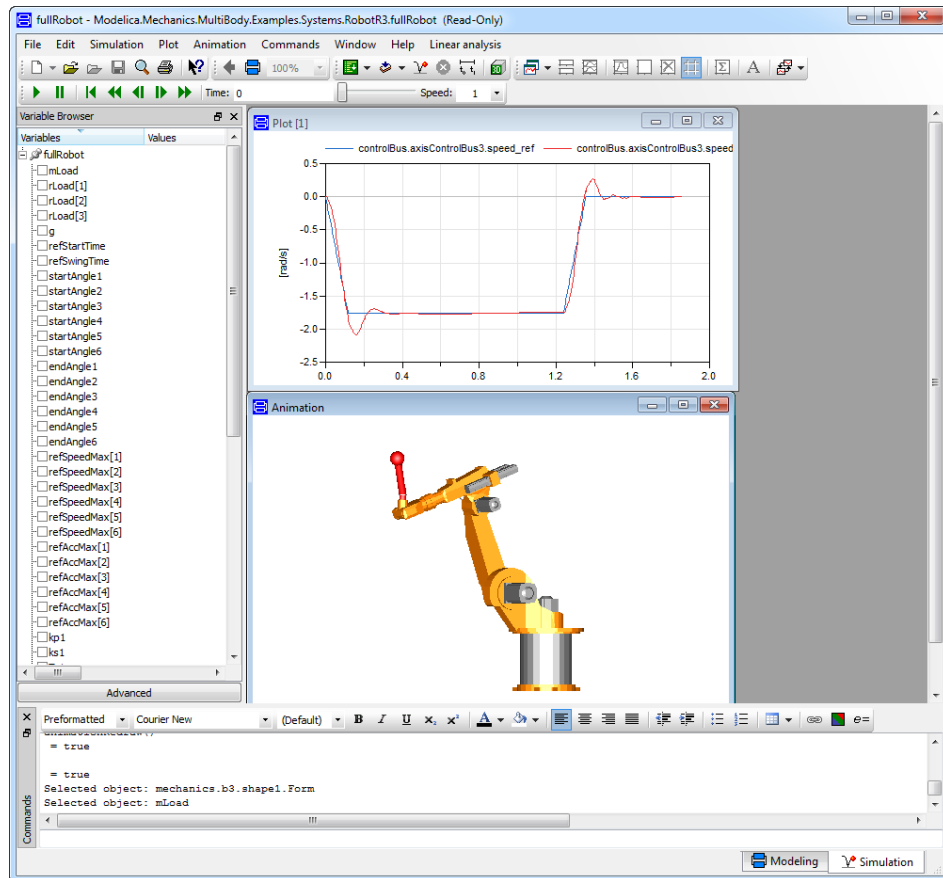

The Simulation menu contains commands to setup and run simulations. Shortcut buttons are also available. However, the demo has also been prepared with a command script that will simulate the model. The script is executed selecting **Commands > Simulate**. Please use that command.

**Simulating the demo
(by running a script).**

The model is now translated and simulated automatically. The script also contains some setting of a plot window and an animation window. After enlarging the Dymola main window it will look the following:

**Animated 3D view of
the robot.**

Let us start to animate the robot. Start the animation by selecting **Animation > Run** or clicking the **Run** button on the toolbar (the leftmost button)

Animation toolbar.

This toolbar contains the usual buttons of running, pausing, rewinding, and stepping forward and backward, respectively. Also the time flow is shown and there is a possibility to set the speed of the animation (higher figures means higher speed)

Please note that the Animation window can be maximized in the main window in the usual way.

If the Animation window by mistake is deleted, a new can be displayed using the command **Animation > New Animation Window**.

Direct manipulation of the view in the animation window using the mouse has been implemented. The view can be moved, rotated and zoomed using mouse movements in combination with Meta keys:

Operation	Meta key	Mouse move (dragging)	Arrow keys
Moving up/down/left/right	none	Up/Down/Left/Right	Up/Down/Left/Right
Tilt (Rotate around x-axis)	Ctrl	Up/Down	Up/Down
Pan (Rotate around y-axis)	Ctrl	Left/Right	Left/Right
Roll (rotate around z-axis)	Ctrl+Shift	Clockwise/Counter-clockwise	Left/Right
Zoom in/out	Shift	Up/Down	Up/Down
Zoom in/out	none	Wheel	
Zoom in/out	Ctrl	Wheel	
Zoom in/out	Ctrl	Right mouse button Up/Down	

To set the rotation center on a selected component, use the context menu of the object and select **Current Object > Set Rotation Center**.

The arrow keys pan and tilt in fixed increments of 5 degrees, in addition **page up/page down** tilt 45 degrees. The **Home** key resets viewing transformation.

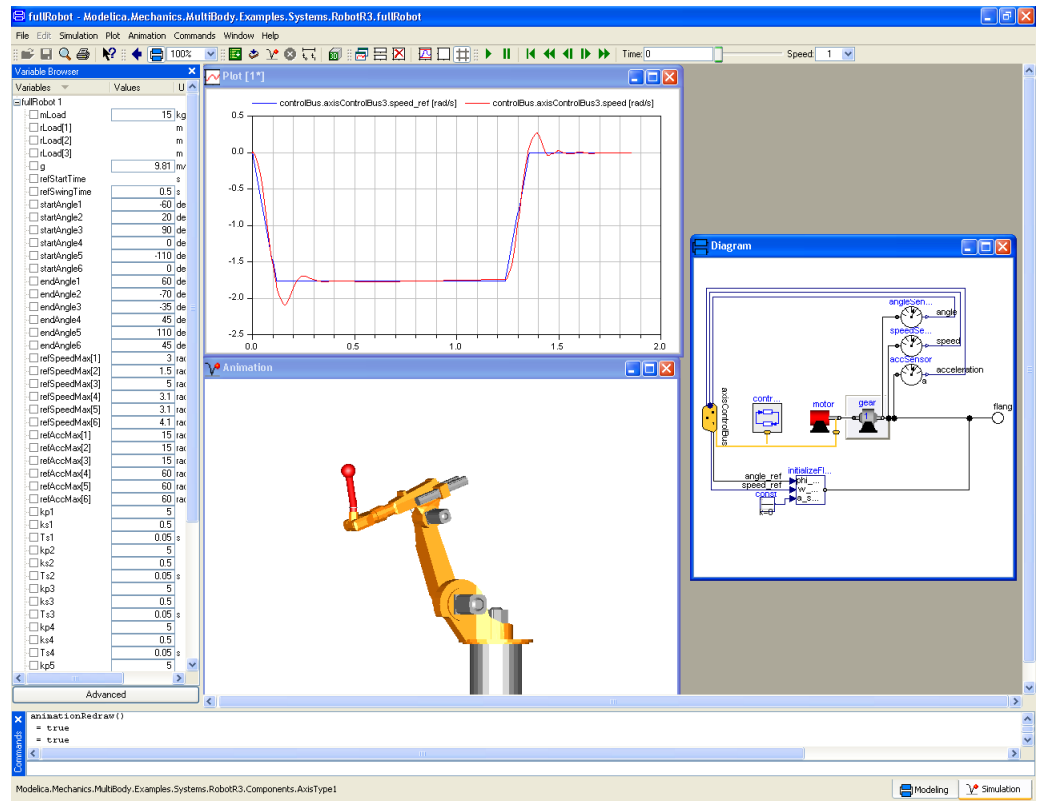

Let us now look at the plot window. The plot shows the speed reference and actual speed of the third joint.

A very convenient way to display the variables for a certain component that is of interest is to use the diagram layer of the edit window also in Simulation mode. The diagram layer enables the user to follow a simulation by displaying variables and to control it by setting parameters. The user can descend into any level of the model in order to plot or display variables.

Push the **Diagram layer** button  in the diagram layer toolbar to show the diagram. The result might look like:

The diagram layer in Simulation mode.

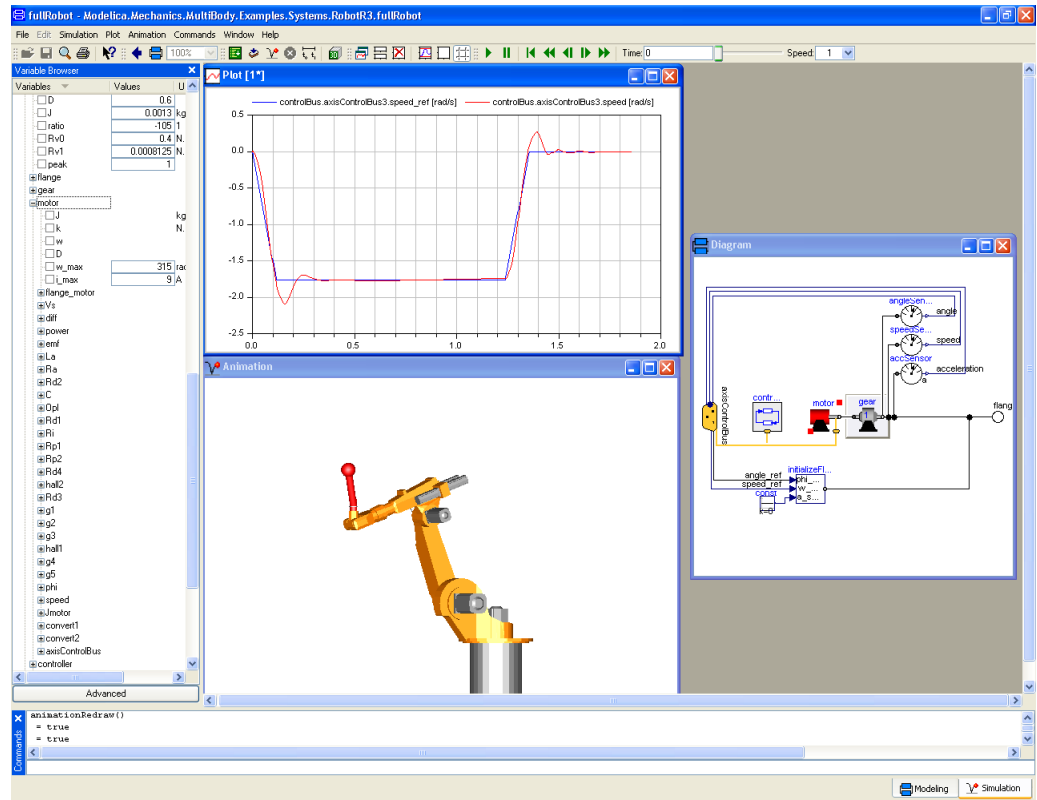

Now the diagram layer is visible. You can now navigate exactly the same way as in the Modeling mode – right-click on the component you want to look into and select **Show Component** to look into it.

You go back using the **Previous**  button in the diagram layer toolbar .

If you want the diagram layer to show more of an overview; e.g. the whole robot, you have to go back to Modeling mode and change what is displayed in the Edit window. Then you can go back to Simulate mode.

When having reached the interesting component, right-click on it and select **Show Variables**, which will open and highlight the selected component instance in the variable browser. In the figure below, the variables of the motor in Axis 1 is displayed in this way.

Using the diagram layer to select variables to be shown.

Please note that if the diagram layer window is active, selecting another component in the variable browser will also change the selection in the diagram layer window.

Changing and saving start values

Using the variable browser you can change values, and then simulate again. It is possible to save changed start values directly into the model, see section “Saving changed start values to the model” on page 67 for more information about this possibility.

1.2.3 Other demo examples

Other demo examples can be found under the **File > Demos** menu. After selecting an example, it can be simulated by running a corresponding script file as was done for the robot example. The exception is the demos in Automotive Demos Library. It contains several demos, and the relevant demo has to be opened first by expanding the package “Examples” in the package browser by clicking the + before it, and then double-clicking on the relevant demo to open it. Please note that to run any of the Automotive Library demos you have to have a number of licenses for commercial libraries. Please see the description presented when opening the library for more information.

1.3 Solving a non-linear differential equation

This example will show how to define a simple model given by an ordinary differential equation. We will simulate a planar mathematical pendulum as shown in the figure.

A pendulum.

The variable m is the mass and L is the distance from the support to the center of mass. Let us assume the string is inextensible and massless, and further, let us neglect the resistance of the air and assume the gravitational field to be constant with g as the acceleration of gravity. The equation of motion for the pendulum is given by the torque balance around the origin as

$$J \cdot \text{der}(w) = -m \cdot g \cdot L \cdot \sin(\text{phi})$$

where J is the moment of inertia with respect to the origin. Assuming a point mass gives

$$J = m \cdot L^2$$

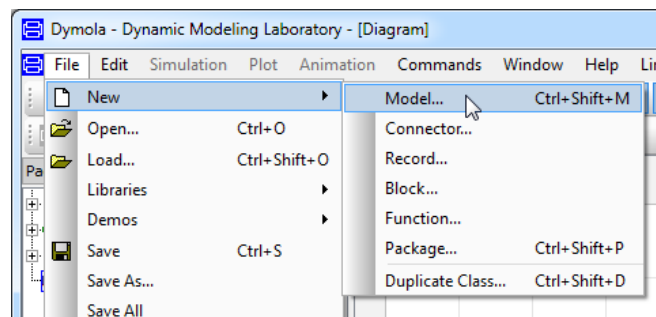

The variable w is the angular velocity and $\text{der}(w)$ denotes the time derivative of w , i.e., the angular acceleration. For the angular position we have

$$\text{der}(\text{phi}) = w$$

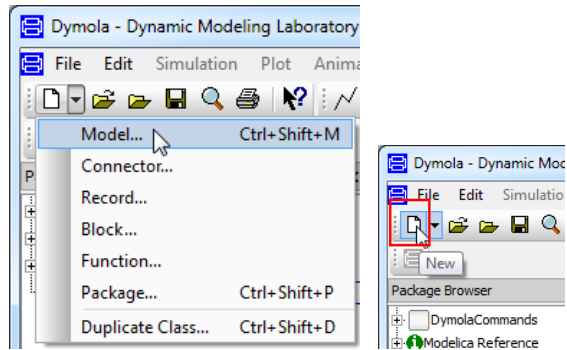

Start Dymola or if it is already started then give the command **File > Clear All** in the Dymola main window.

Click on the tab **Modeling** at the bottom right. Then select **File > New > Model...**

The first step to create a new model.

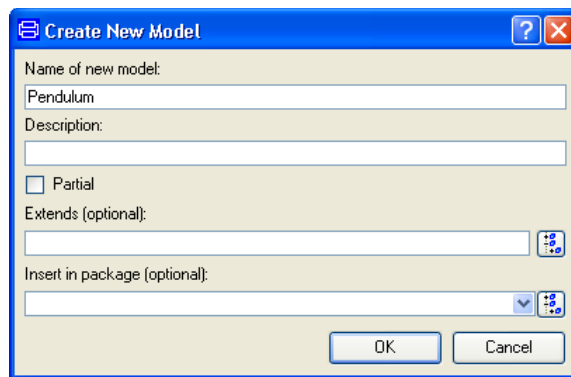

(You can also perform the opening command either by clicking the arrow on the **New** command button and select **Model...**, or click the command button **New** directly (**Model...** is the default selection in that case.))

Having several alternatives doing the same thing is not uncommon in Dymola.)

A dialog window opens. Enter **Pendulum** as the name of the model.

The dialog to name a new model component.

Click **OK**. You will then have to **Accept** that you want to add this at the top-level. You should in general store your models into packages, as will be described later.

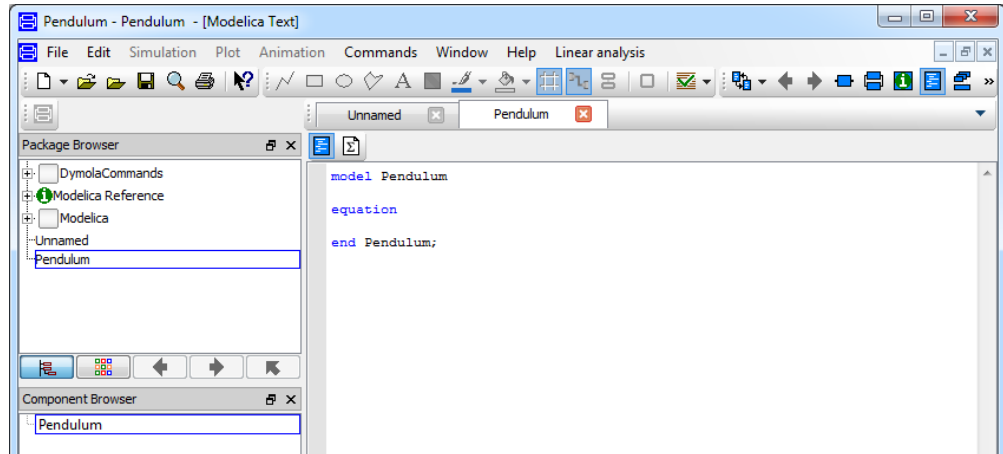

Since you use the **New** command, a new tab will be opened with the new model. The tabs work like working areas in for example Internet Explorer.

A model can be inspected and edited in different views. When specifying a behavior directly in terms of equations, it is most convenient to work with the model as the Modelica Text; that is, working in the Modelica text layer of the edit window.

To display this layer, press the **Modelica Text** toolbar button (the second rightmost tool button). The edit window can now be used as a text editor.

The model presented in the Modelica text layer.

To declare the parameters and the variables, enter as shown the declarations for the parameters m , L and g , which also are given default values. The parameter J is bound in terms of other parameters. Finally, the time varying variables ϕ and w are declared. A start value is given for ϕ , while w is implicitly given a start value of zero.

```

model Pendulum
  parameter Real m=1;
  parameter Real L=1;
  parameter Real g=9.81;
  parameter Real J=m*L^2;
  Real phi(start=0.1);
  Real w;
equation
  der(phi) = w;
  J*der(w) = -m*g*L*sin(phi);
end Pendulum;

```

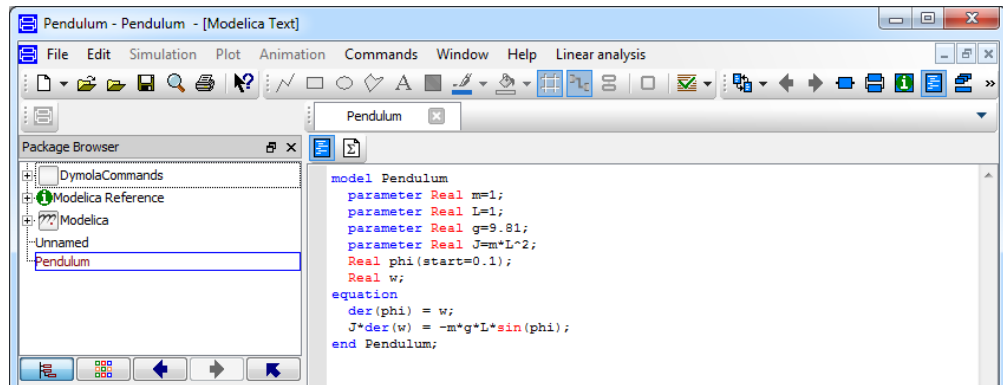

New text will be syntax highlighted (color coded) as you type, except types; e.g. Real. To get also types color coded, right-click and select **Highlight Syntax** or press **Ctrl+L**. Apart from implementing color codes for types, the command will also give a message if the syntax is not correct. It is a good idea to use the command regularly. The command does not, however, change the formatting of the text (tabs etc.). Such change is implemented by selecting the part of the text that should be reformatted, and then right-clicking and selecting **Reformat Selection** (or press **Ctrl+Shift+L**).

The color codes are:

blue	keywords
red	types, operators etc.
black	values, variables, parameters etc.
green	comments

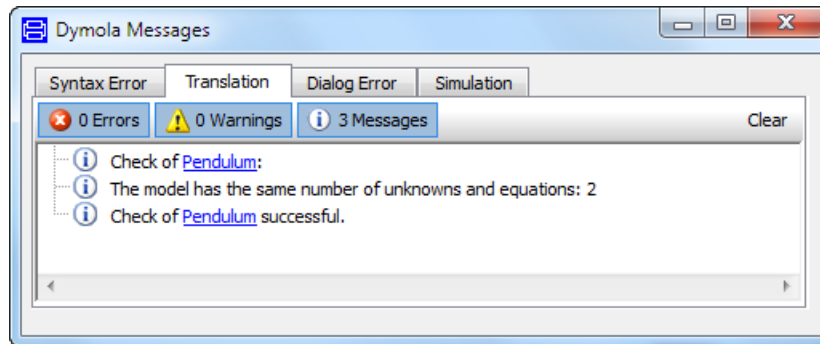

If the text seems too small to work with, the text size can be changed using the **Edit > Options...** command and temporary changing the **Base font size** in the **Appearance** tab. It is a good idea to set it back afterwards.

Declaration of parameters, variables and equations.

Since the model should be simulated, it should be checked before saved. The check command performs some symbolic and syntactic checks that will capture a number of errors that might have been introduced by the user. The check can be made clicking on the **Check** icon or by selecting the command **Edit > Check** or by using the **F8** function key. The result of a check of the above text looks the following:

Check of model.

The model is now ready to be saved. Select **File > Save**. Call the file pendulum and keep the file extension to .mo and place it in a working directory.

1.3.1 Simulation

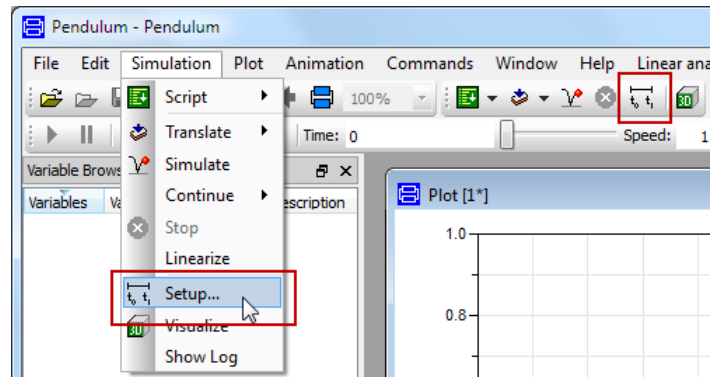

Now it is time to simulate. To enter the simulation mode, click on the tab **Simulation** at the bottom right of the main window. The simulation menu is now activated and new toolbar buttons appear.

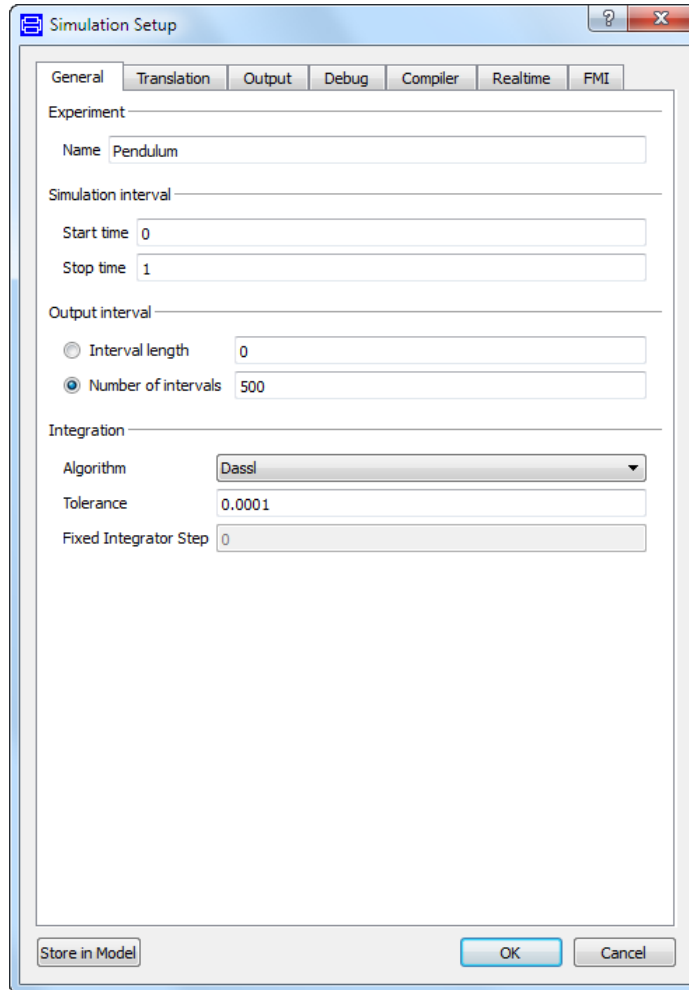

Selecting Setup in the Simulation menu.

To set up the simulation select **Simulation > Setup...** or click directly on the **Setup** toolbar button.

The simulation setup menu will be displayed:

The Simulation Setup menu.

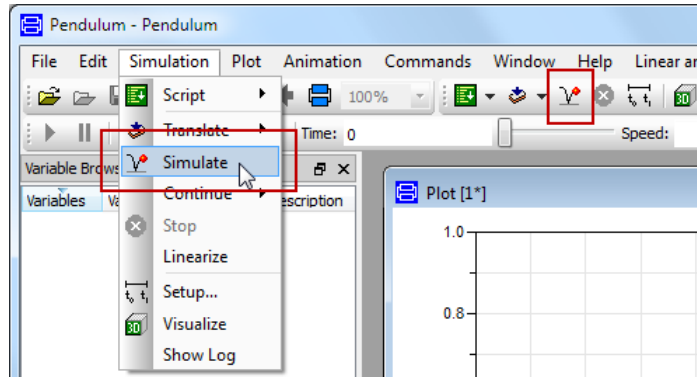

Set the **Stop time** to 10 seconds. Click **OK**.

To run the simulation select **Simulation > Simulate** or click directly on the **Simulate** toolbar button.

Selecting Simulate in the Simulation menu.

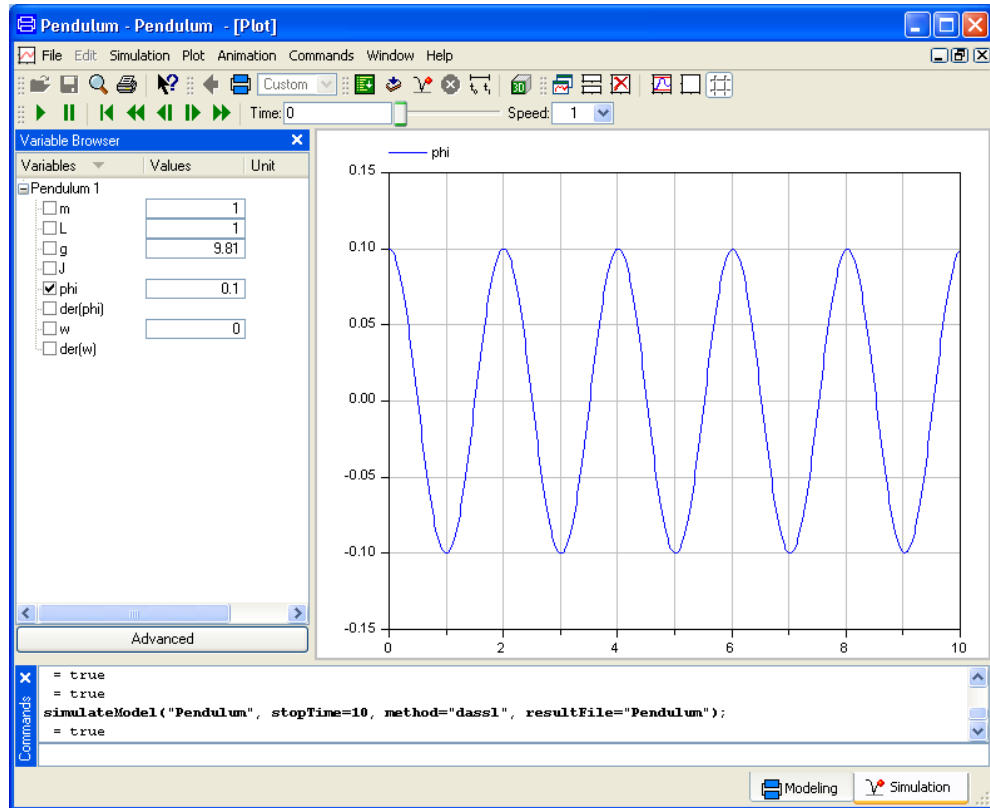

Dymola first translates and manipulates the model and model equations to a form suitable for efficient simulation and then runs the simulation. (You may explicitly invoke translation yourself by selecting **Simulation > Translate** or click on the **Translate** toolbar button.)

You will get a warning that the initial conditions are not fully specified. (The warning can be seen in the Translation tab of the Message window that will pop.) However, Dymola will select default initial conditions, so the simulation will work. We will discuss how to get rid of the warnings later. For now, you can just close the Message window.

When the simulation is finished, the variable browser displays variables to plot. To see the plot better, maximize the plot window in the edit window. Then click in the square box in front of ϕ to get the angle plotted as shown below.

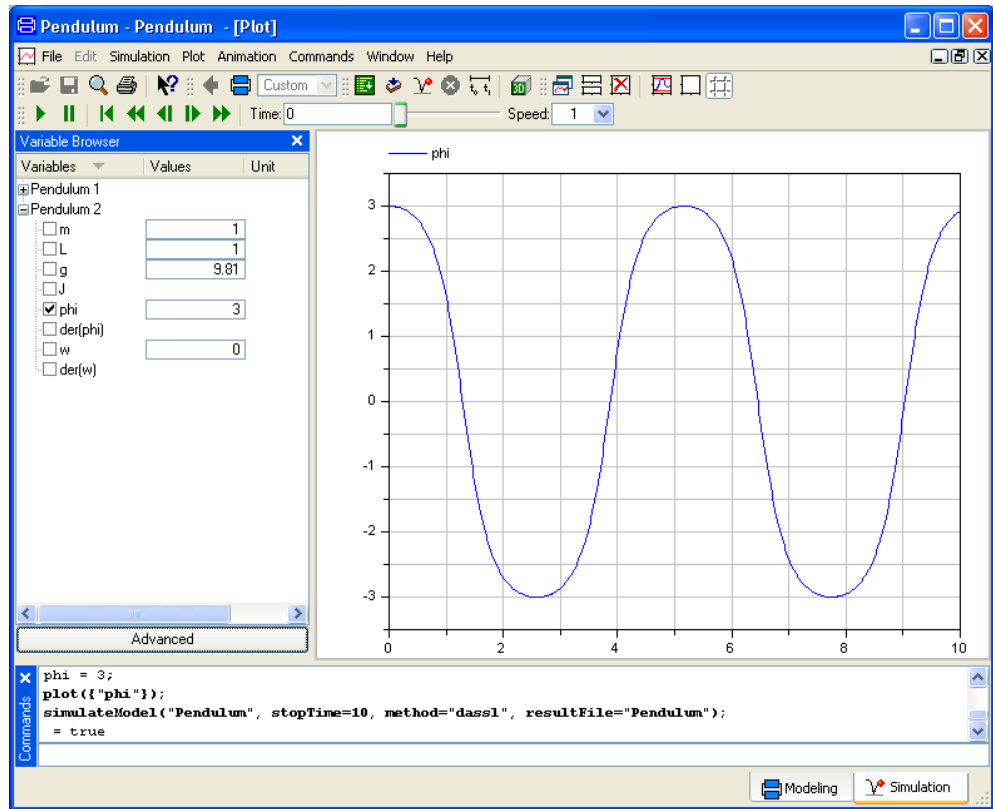

Plotting the angle.

Let us study a swing pendulum with larger amplitude and let it start in almost the top position with $\phi = 3$. It is easy to change initial conditions. Just enter 3 in the value box for ϕ and click on the **Simulate** tool button.

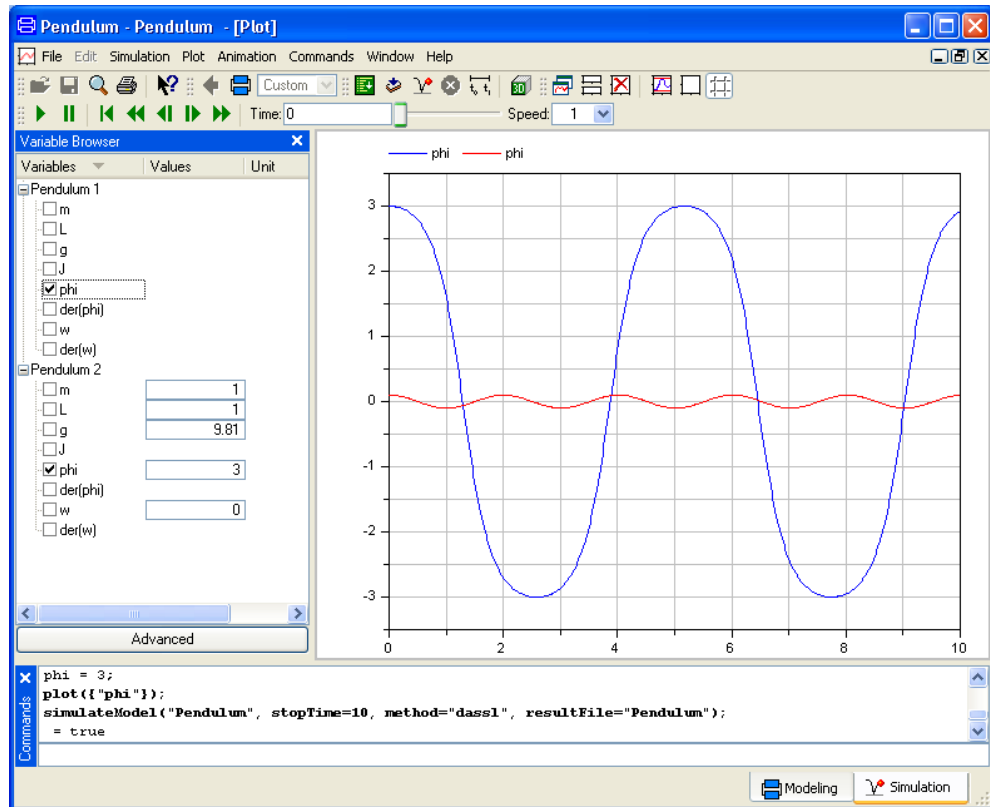

You can also change start values and parameters by typing in the command window; e.g. type $\phi=3$ (followed by carriage return) for a change of ϕ .

Pendulum angle when starting in almost the top position.

The results of previous simulations are available as the experiment Pendulum 1 in the Variable browser. We can open it up and have phi of the two runs plotted in the same diagram by expanding “Pendulum 1” in the variable browser and check the checkbox for “phi”.

Results from two simulations.

Values of parameters are changed in a similar way. To simulate another length of the pendulum, just enter a new value for L and click on the simulate button.

1.3.2 Improving the model

Using pre-defined physical quantities

The parameters and variables are more than real numbers. They are physical quantities. The Modelica standard library provides type declarations for many physical quantities. Using these instead of declaring variables/parameters yourself gives two advantages:

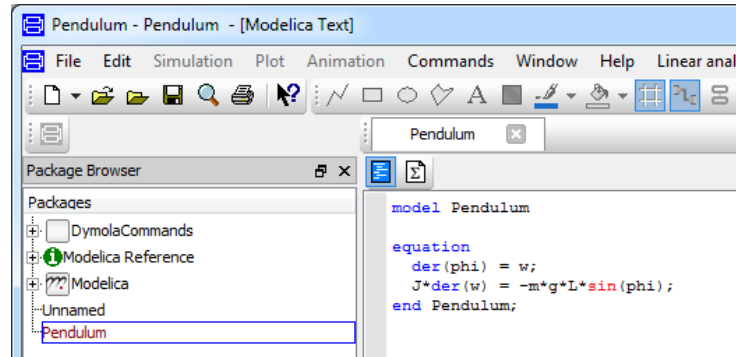

- The declarations will be faster.
- Additional features will automatically be present; e.g. units and limits.

So let us change the model, using ready-made physical quantities. The starting point is the Pendulum model built previously. (If Dymola is not started, start it and use **File > Open** to open Pendulum.mo.)

Press the **Modelica Text** toolbar button (the second rightmost tool button) to show the Modelica text layer.

Mark the declarations of variables/parameters in the text and delete them. Do not delete the equation, that one we will keep. The result will be:

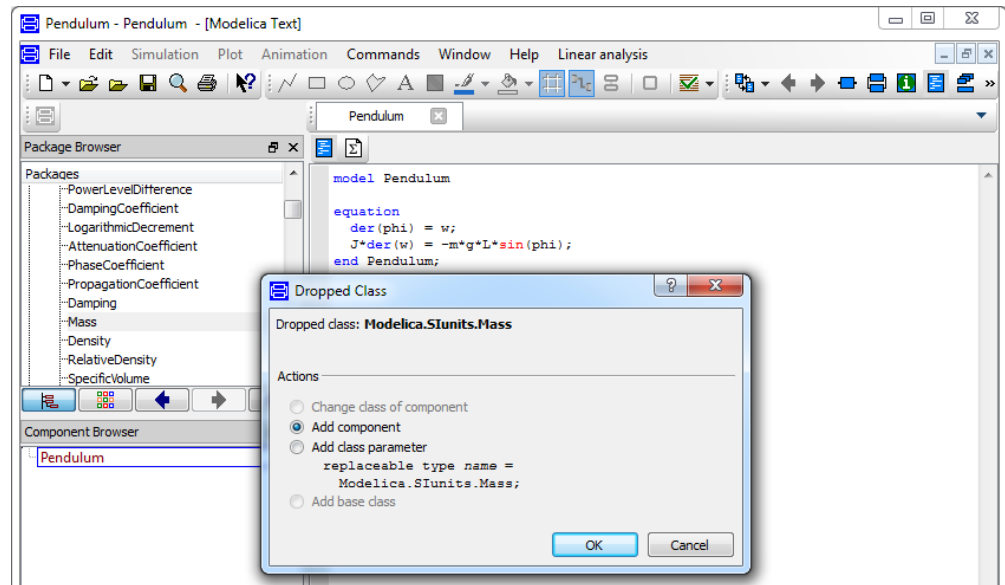

Open Modelica.SIunits in the package browser by first expanding the Modelica package by clicking on the + in front of it and then expanding “SIunits” by clicking on the + in front of it. Now a number of physical types should be visible.

What is to be done is to redo the declaration part of the model presented on page 22 using the physical types available in Modelica.SIunits. The mass is the first one to be declared. To find “Mass” in the package browser, click on the package “SIunits” (to get a good starting point) and then press **m** on the keyboard. The first physical type starting with “m” will be displayed. Pressing **m** again will find the next physical type starting with “m” and so on. (Another way to find it fast is by clicking on the header “Packages” of the package browser, that will sort the physical types in alphabetical order.)

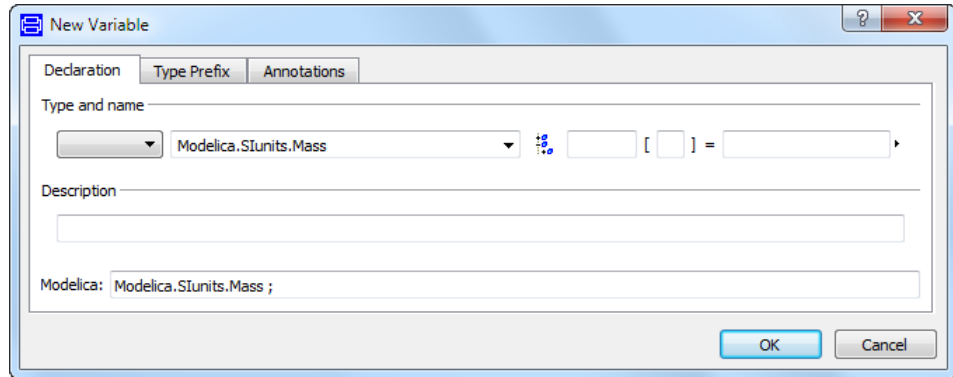

Once “Mass” is found, drag it to the component browser. The following menu will pop up:

Adding a physical type.

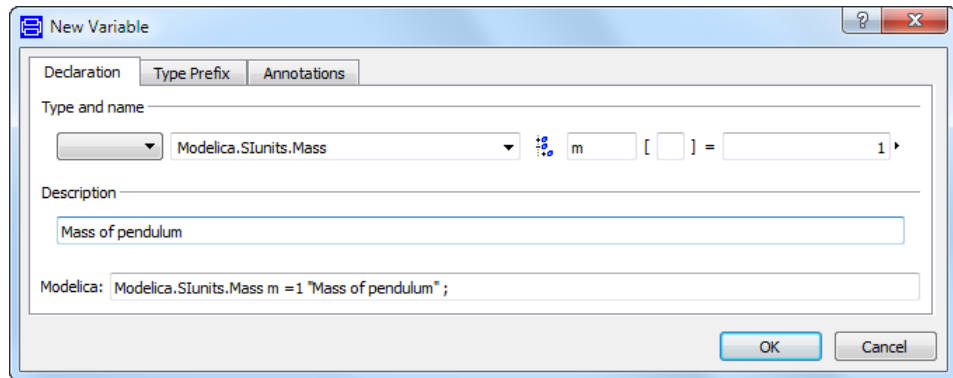

The choice to add a component is pre-selected. Click **OK**. A menu to declare a variable pops up:

Declaring a variable.

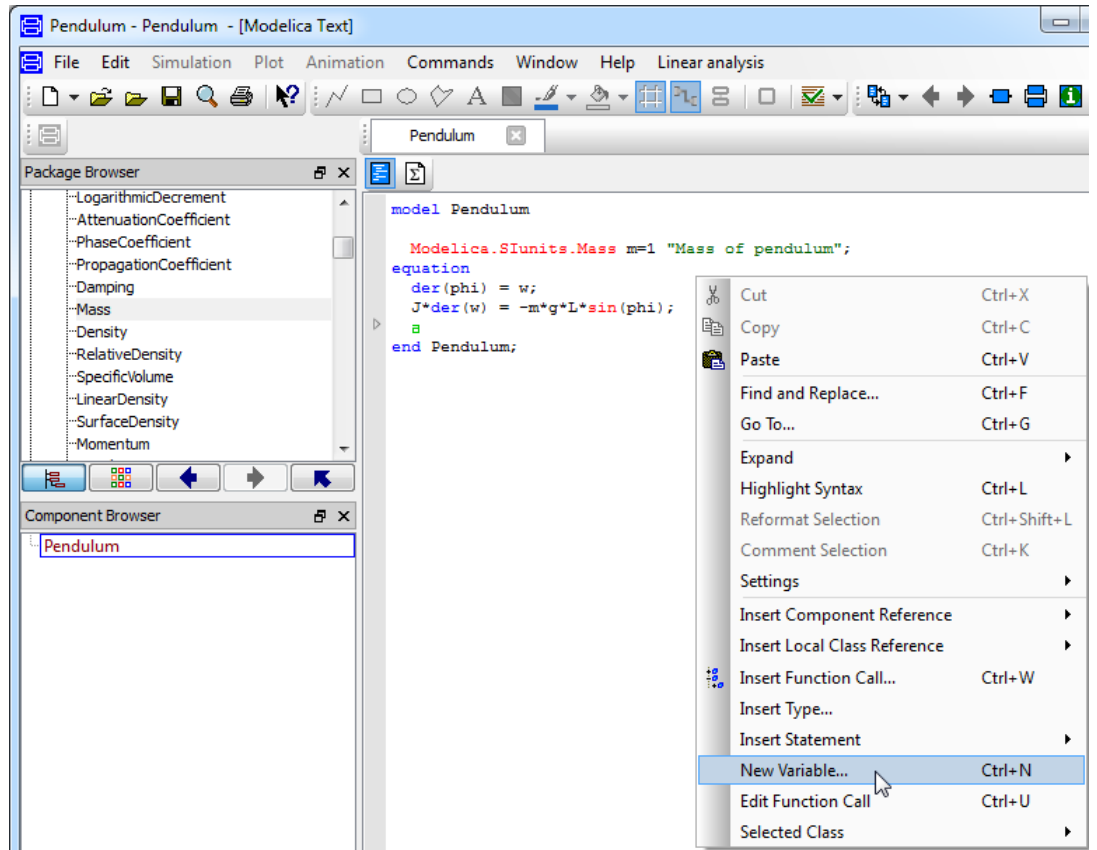

Now we can specify the type prefix (parameter), the name, value and description etc. (By keeping the cursor on top of an input field for a while a tooltip text pops up explaining the field.) Complete the description in the following way:

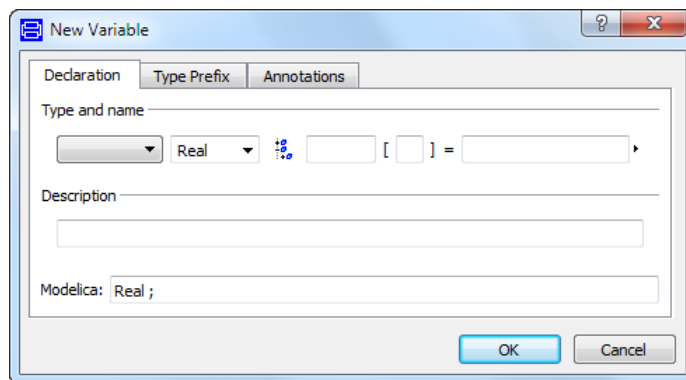

Click **OK** and the text appearing in the bottom row is inserted into the Modelica text window.

You can also declare variables by using menu commands. Let us define the next parameter by right-clicking in the Modelica Text layer and select **New Variable...**

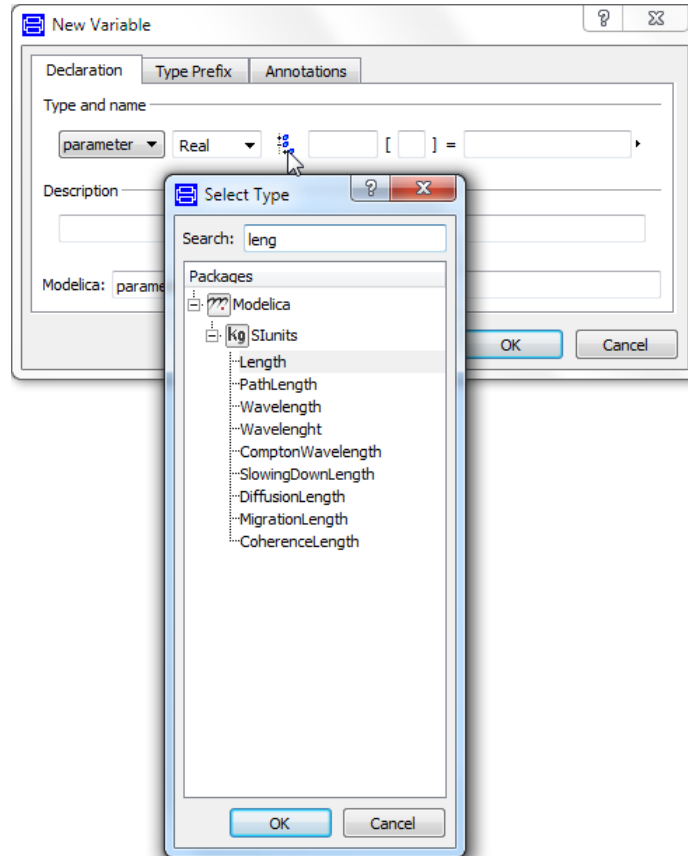

The result is the declaration dialog, just as before:

After having selected “parameter” from the dropdown menu, we realize that the default type “Real” is not what we want in this case; neither are any of the other dropdown alternatives relevant for us. What we really would like is some “length” type. However, we can browse for any type available in the package browser by the browse button. And, on top of that, we

can type in the **Search** input field. The search is dynamically updated while typing. This is illustrated in this figure:

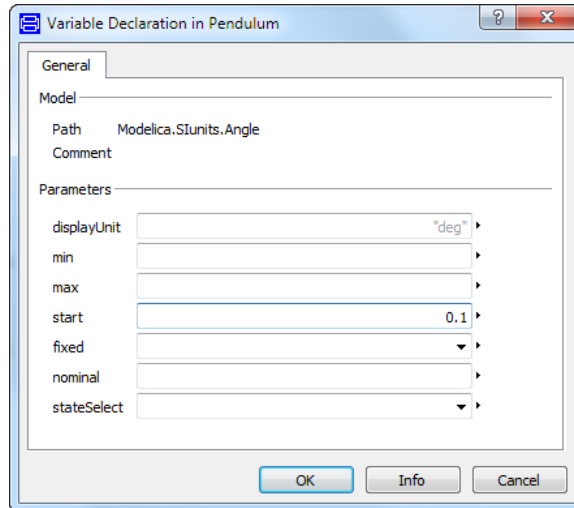

This was exactly what we wanted. It is sufficient to click **OK** to get the type, since it is preselected. (If we wanted another of the displayed types, we could have selected that before clicking **OK**.)

It should be noted that the way above is available also when the Modelica Text layer is not displayed; the command **Edit > Variables > New Variable...** is always available.

The other quantities are defined in analogue ways. (It is a good idea to try both ways above to see which one you like the best.) When coming to the variables “phi” and “w”, they are variables, not parameters. Nothing should be entered in the type prefix input field for those.

When completing the form to declare the angle phi, the start value of the angle is defined by clicking on the small triangle to the right of the value field and selecting **Edit**. A submenu pops up. Enter 0.1 for start. The result will look like:

Entering a start value.

Click **OK**.

The following result is displayed:

The result.

```
model Pendulum
  parameter Modelica.SIunits.Mass m=1 "Mass of pendulum";
  parameter Modelica.SIunits.Length L=1 "Lenght of the pendulum";
  parameter Modelica.SIunits.Acceleration g=9.81 "Gravity of acceleration";
  parameter Modelica.SIunits.MomentOfInertia J=m*L^2 "Moment of inertia";
  Modelica.SIunits.Angle phi(start=0.1) "Pendulum angle";
  Modelica.SIunits.AngularVelocity w "Angular velocity";
equation
  der(phi) = w;
  J*der(w) = -m*g*L*sin(phi);
  +;
end Pendulum;
```

The “+” in the margin to the left of the text and the icon almost at the end of the text indicates the presence of graphical information or annotations. It may be displayed. This can be done in two ways, either by clicking on the “+” or on the icon, or by right-clicking to get the context menu, and then select **Expand > Show Entire Text**. Either way, it is revealed that the annotation is an annotation documenting which version of the Modelica standard library was used. Dymola uses this information to check if compatible versions of libraries are used and to support automatic upgrading of models to new versions of libraries. A model developer can provide conversion scripts that specify how models shall be upgraded automatically to new versions of a library.

Please note that if any parameter/variable should be changed later on, the command **Edit > Variables** can be used to select the variable that should be edited.

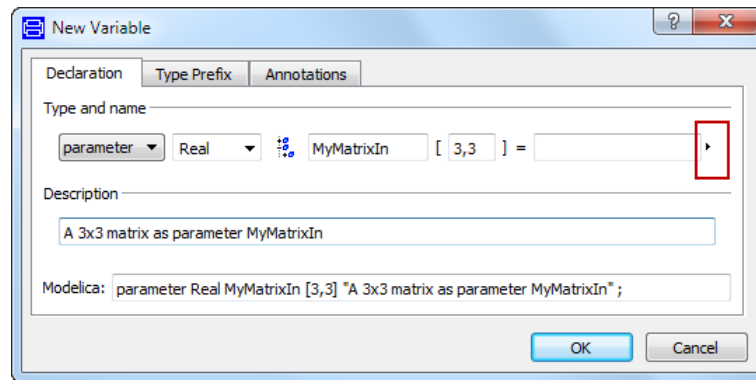

(Another way of inserting pre-defined physical quantities is to recognize that these are types. Types can be inserted in the code by right-clicking to pop the context menu and then selecting **Insert Type**. The menu that pops enables searching by typing in names. The advantage is that all types in all open packages are searched. It will be easy to find a known type even if it located in another package. However, to also get help from the **Declare variable** menu as above, the user has to

- Insert the type on an empty line
- Enter a space and the name of the variable
- Conclude with a semicolon
- Use **Edit > Variables** and select the new variable)

Example of defining a 3 x 3 matrix Real parameter.

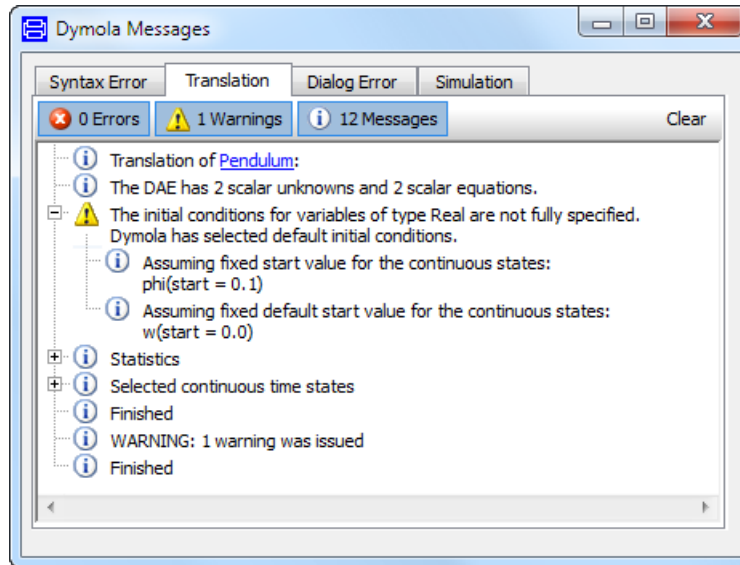

Note (outside the example) the ease of defining arrays/matrices using **Edit > Variables > New Variable....** In the Declare Variable dialog that is displayed, an “Array dimensions” field is present after the “Variable Name” field. By entering “3” in this field, an array containing 3 elements is defined, entering “:” defines an expandable array. Entering “3,3” defines a 3 x 3 matrix, entering “:,:” defines an expandable matrix.

To enter values or/and define the size, click on the arrow after the last field (see red marking in the figure above), then on the **Edit** command . You will get a dialog to enter the values.

Handling of warnings

When simulating, we still get a warning that the initial conditions are not fully specified. By clicking on the **Translation** tab in the Message window and scroll to the top the following can be seen (when you have expanded “the warning” node by clicking on the “+” before it):

In order to have sufficient number of initial conditions, Dymola look at the possibility to use variables as states and attribute fixed start values to such states. (For more information, please see chapter “Introduction to Modelica”, section “Initialization of models” and (more advanced) the manual “Dymola User Manual Volume 2”, chapter “Advanced Modelica support”, section “Means to control the selection of states”.)

Dymola presents in the warnings what variables have been selected as states with fixed start values.

Dymola assumes fixed start values $\phi=0.1$ and $w=0$. We have set the start value of ϕ to 0.1 (above), while the start value of w was implicitly given a start value of zero (default). However, the attribute fixed is the problem. Fixed=true means that the start value is used to initialize the model; it must be satisfied during initialization. Fixed=false means that the value is just a guess-value for a non-linear solver. For variables fixed is default false. Since the intention was to use these variable values as initialization values, the best is to explicitly set the fixed-attribute to true – and also explicitly specify the start value of w to zero. The resulting code (generating no warnings) will be:

```

model Pendulum
  parameter Modelica.SIunits.Mass m=1 "Mass of the pendulum";
  parameter Modelica.SIunits.Length L=1 "Lenght of the pendulum";
  parameter Modelica.SIunits.Acceleration g=9.81 "Gravity of acceleration";
  parameter Modelica.SIunits.MomentOfInertia J=m*L^2 "Moment of inertia";
  Modelica.SIunits.Angle phi(start=0.1, fixed=true) "Pendulum angle";
  Modelica.SIunits.AngularVelocity w(start=0, fixed=true) "Angular velocity";
equation
  der(phi) = w;
  J*der(w) = -m*g*L*sin(phi);
end Pendulum;

```

1.4 Using the Modelica Standard Library

In this example, we will show how a model is built up using components from the Modelica Standard Library. The task is to model a motor drive with an electric DC motor, gearbox, load, and controller.

Motor drive built with standard components.

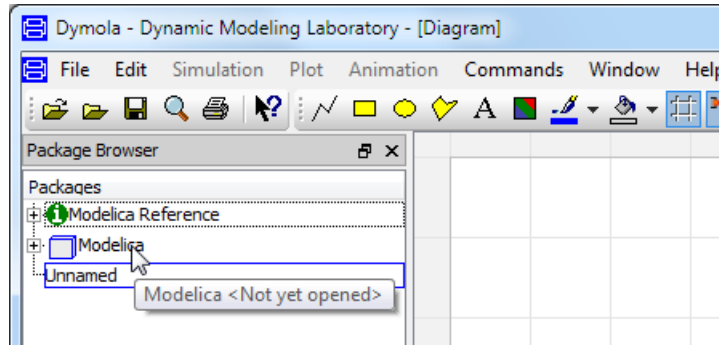

As when building a real system, there are several approaches. One extreme approach is to build the system from scratch. However, it is often a difficult and time-consuming task. Another approach is to investigate if the system already is available on the market or if there is some product that easily can be adapted or modified. If not, build the system from components available when possible and develop only when necessary.

The idea of object oriented modeling is to support easy and flexible reuse of model knowledge. Modelica has been designed to support reuse of model components as parts in different models and to support easy adaptation of model components to make them describe similar physical components. The design of Modelica has also been accompanied by the development of model libraries.

1.4.1 The Modelica Standard Library

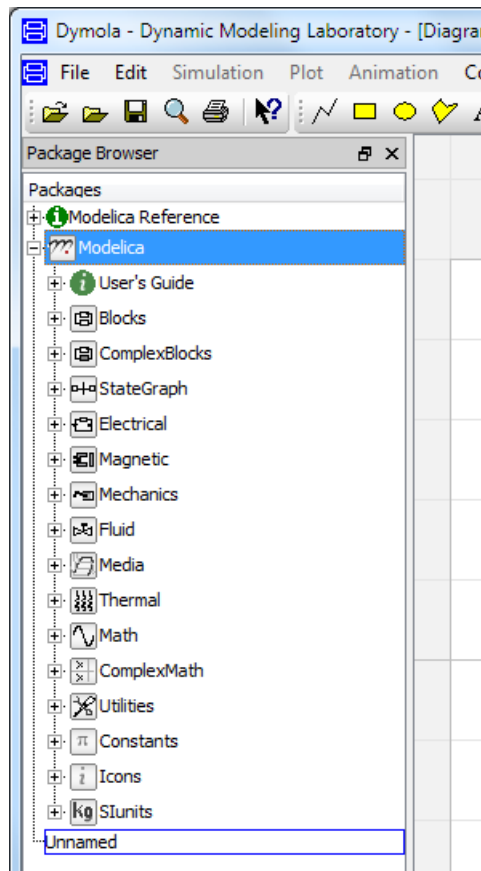

We will now have a look at the Modelica Standard Library to see what is available and how we access the model components and their documentation. To open the library, double-click on Modelica in the Package browser.

Opening the Modelica Standard Library.

Dymola reads in the library. The Modelica Standard Library is hierarchically structured into sub-libraries.

The sub-libraries of the Modelica Standard Library.

As shown by the package browser, the Modelica Standard Library includes

- **Blocks** with continuous and discrete input/output blocks such as transfer functions, filters, and sources.
- **ComplexBlocks** provides basic input/output control blocks with complex signals. (This library is especially useful e.g. in combination with the library Modelica.Electrical.QuasiStationary in order to build up very fast simulations of electrical circuits with periodic currents and voltages.)
- **StateGraph** for modeling of discrete events and reactive systems by heretical state machines. Please note that a more advanced library is available using the command **File > Libraries > State Graph**. For more information about this library, please see section “Libraries available in the File menu by default” starting on page 82.
- **Electrical** provides electric and electronic components (for analog, digital, machines and multi-phase models) such as resistor, diode, DC motor, MOS and BJT transistor.
- **Magnetic** contains magnetic components to build especially electro-magnetic devices.
- **Mechanics** includes one-dimensional and 3-dimensional translational, rotational and multi-body components such as inertia, gearbox, planetary gear, bearing friction and clutch.
- **Fluid** contains components to model 1-dimensional thermo-fluid flow in network of vessels, pipes, fluid machines, valves and fittings. All media from Modelica.Media can be used. A unique feature is that the component equations and the media models as well as pressure loss and heat transfer correlations are decoupled from each other.
- **Media** includes property models of media.
- **Thermal** provides models for heat transfer and thermo-fluid pipe flow.
- **Math** gives access to mathematical functions such as sin, cos and log and operations on matrices (e.g. norm, solve, eig, exp).
- **ComplexMath** contains complex mathematical functions (e.g. sin, cos) and functions operating on complex vectors.
- **Utilities** contain functions especially for scripting (operating on files, streams, strings and systems).
- **Constants** provide constants from mathematics, machine dependent constants and constants from nature.
- **Icons** provide common graphical layouts (used in the Modelica Standard Library).
- **SIunits** with about 450 type definitions with units, such as Angle, Voltage, and Inertia based on ISO 31-1992.

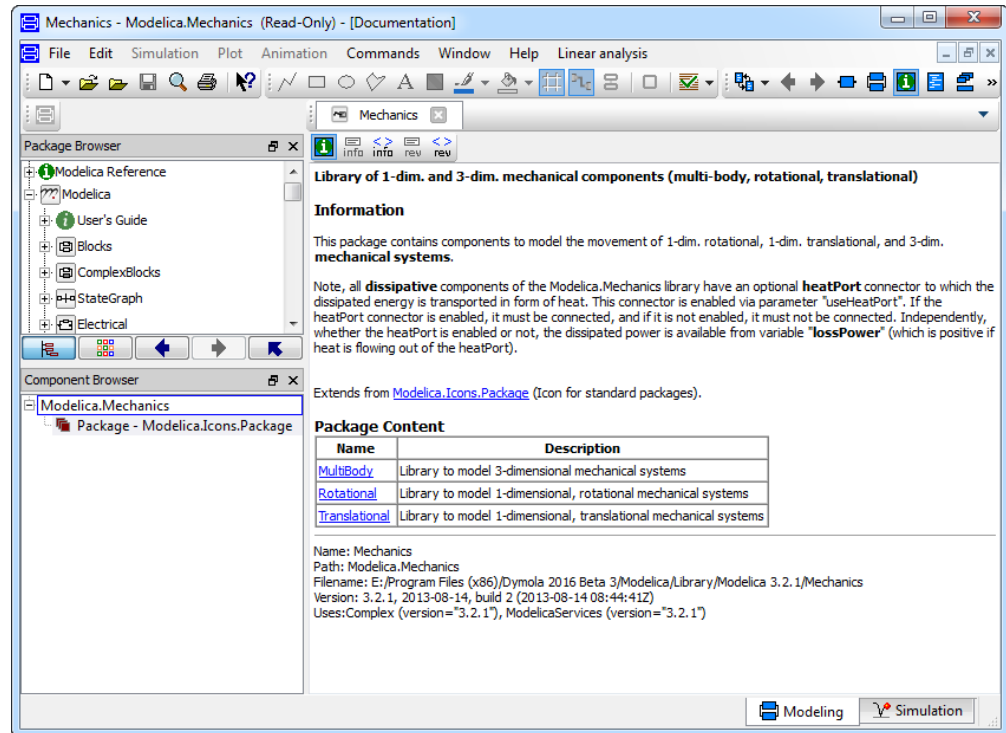

To get documentation for the entire Modelica Standard Library, place the cursor on Modelica, right-click and select **Info**. An information browser is directed to an HTML file containing documentation for Modelica. This documentation has been generated from the Modelica description of the library. There is basic information such as the content of the library, conventions and conditions for use.

Dymola comes also with other free model libraries. A list of these libraries is given by the command **File > Libraries**.

The package menu gives direct access to the sub-libraries. We will need components from various sub-libraries. We will need rotational mechanical components as well as electrical components for the motor.

To open the Modelica.Mechanics, double-click on Mechanics in the Package browser. The documentation layer of the library will be shown. (If not, click on the  in the upper toolbar.)

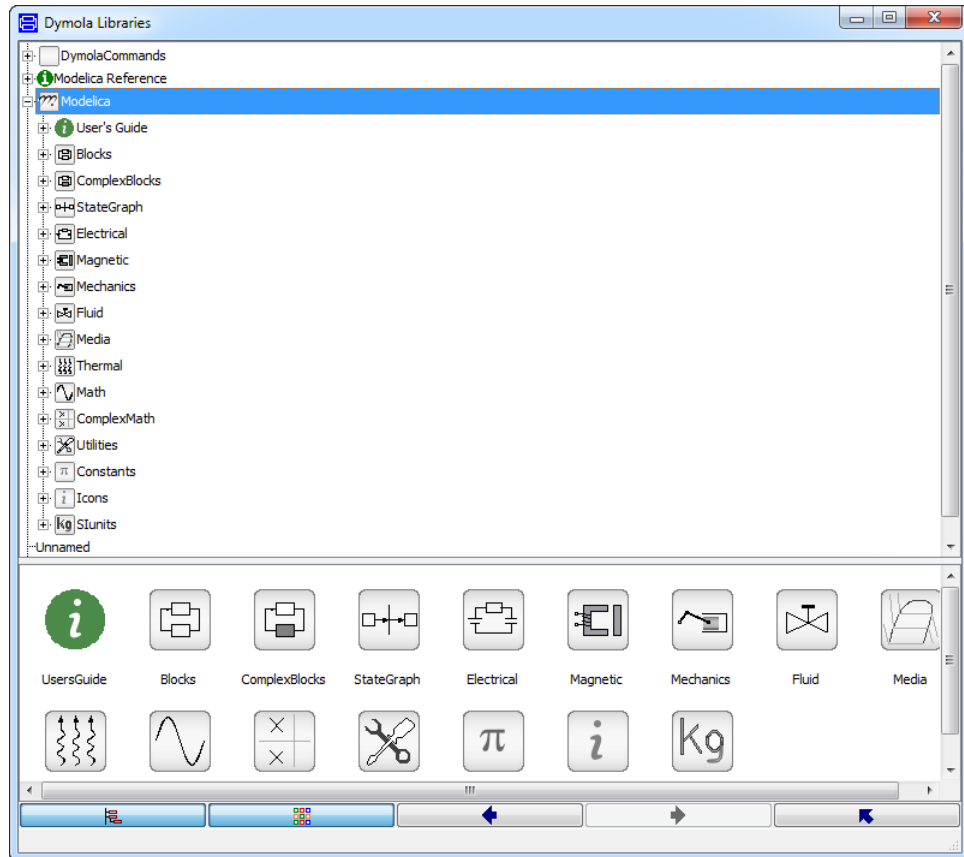

Opening Modelica.Mechanics.

To get documentation on Modelica.Mechanics (as previously demonstrated) place the cursor on Mechanics, right-click and select **Info**.

Besides using the package browser of the Dymola window, it is also possible to open a library window that also contains a browser. It can be done in two ways. If the library window should contain the Mechanics package, select "Mechanics" in the package browser and right-click to get a menu. Select **Open Library Window**. If the window should contain the "top package" in the browser (Modelica in this case), use the toolbar to select **Window > New Library Window**. Using the latter, selecting Modelica in the Package browser in the upper part of the window (and adapting the window) will display the following:

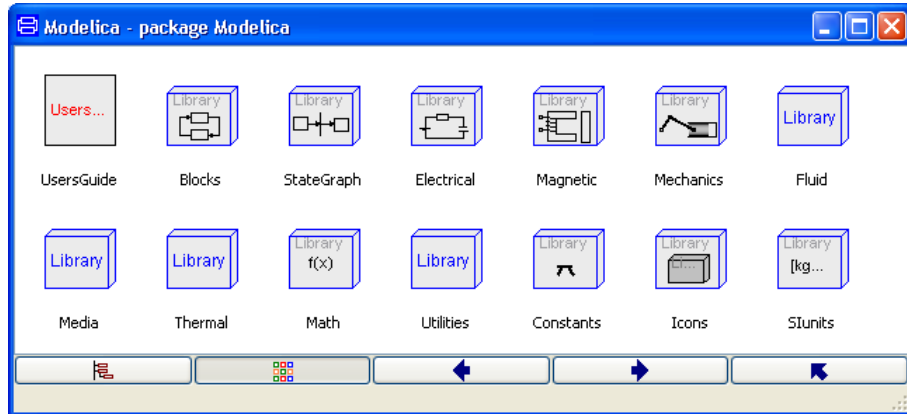

A library window displaying the Modelica Standard Library.

A Library window includes a package browser, where the components of the selected sub-library are displayed in a part of the window.

By closing the package browser by toggling the button to the bottom left, double-clicking on the icon for Modelica and adapting the window to the content the following will be displayed. Please note that now the name of the package will be displayed in the window title bar.

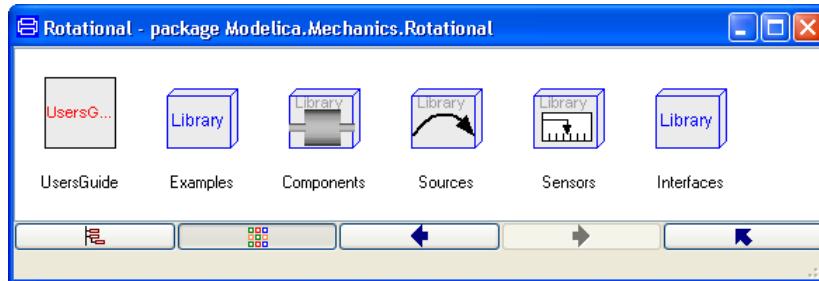

A library window displaying the components of the Modelica Standard Library.

By using the right button at the bottom it is possible to go up in the package hierarchy and by double-clicking on the icons in the window it is possible to go down in the hierarchy. The left and right arrow buttons allow going back and forth as in an ordinary web browser.

Open Modelica.Mechanics.Rotational in the library window by first double-clicking on the icon for Mechanics and then on the icon for Rotational. The package Rotational contains components for rotating elements and gearboxes, which are useful for our modeling of the electrical motor drive.

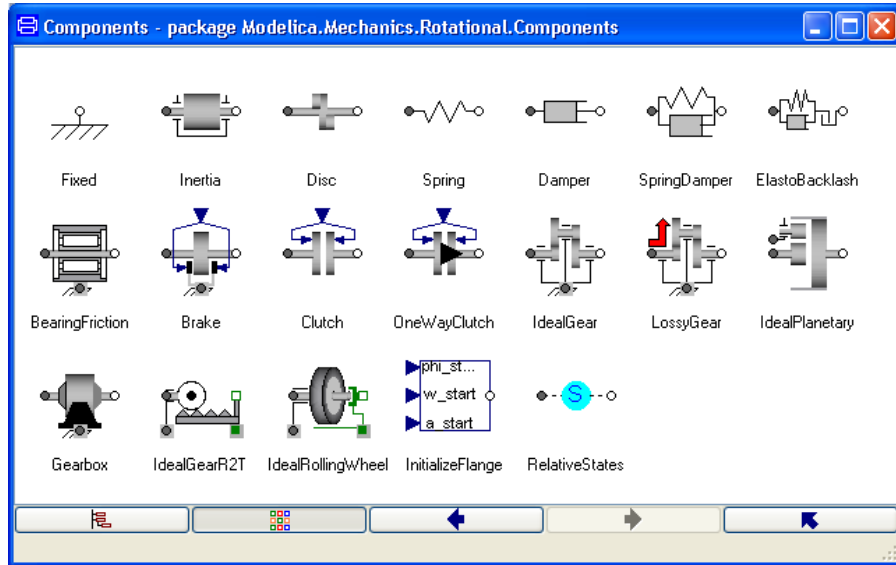

The rotational mechanics library window.

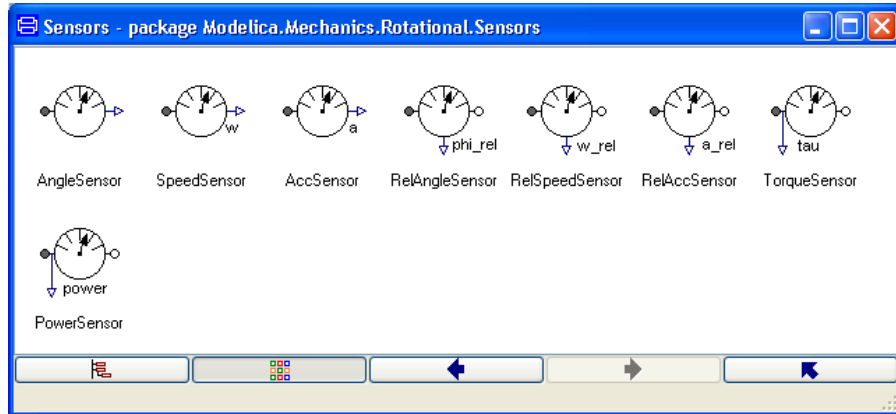

The Info for Modelica.Mechanics.Rotational contains important information on the package content.

By navigating in the packages/libraries present here (using double-clicking and left arrow) we will find a number of components that might be of interest to us. As examples, this is how the libraries Components and Sensors will look like:

The Components library.

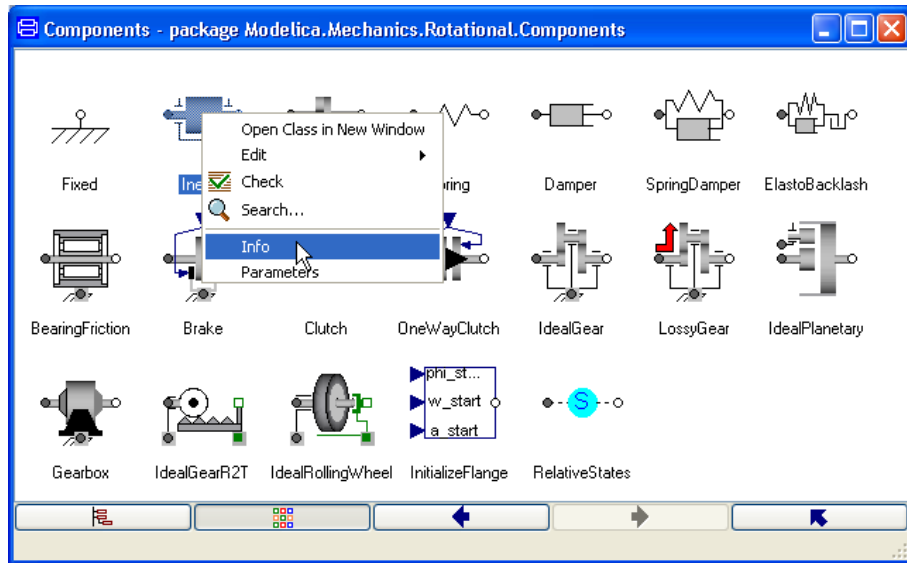

The Sensors library.

A quick scan of the Component library indicates that the model Inertia may be of interest for us.

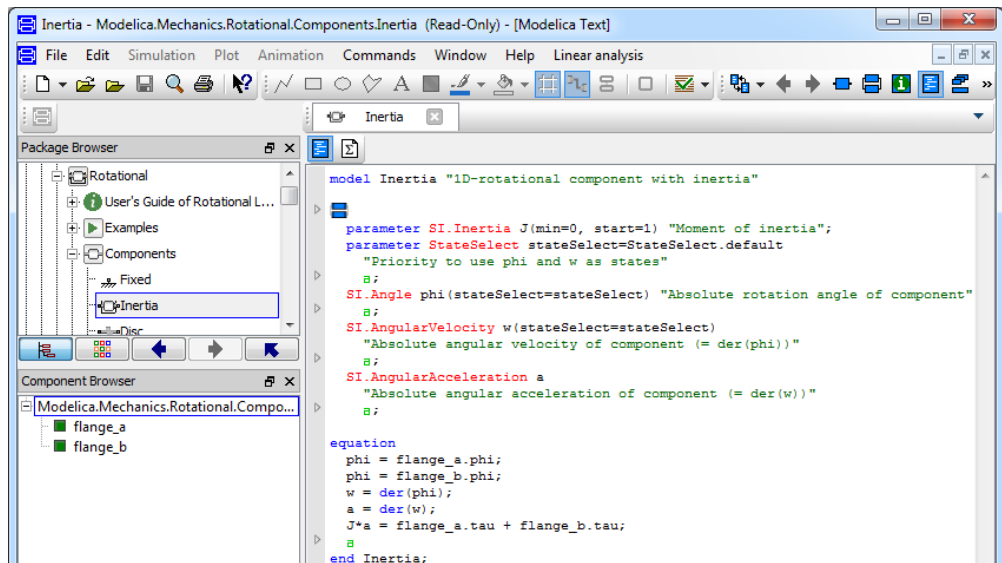

Right-click on Inertia for a context menu. Select **Info** to get documentation for the model.

The context menu for a component.

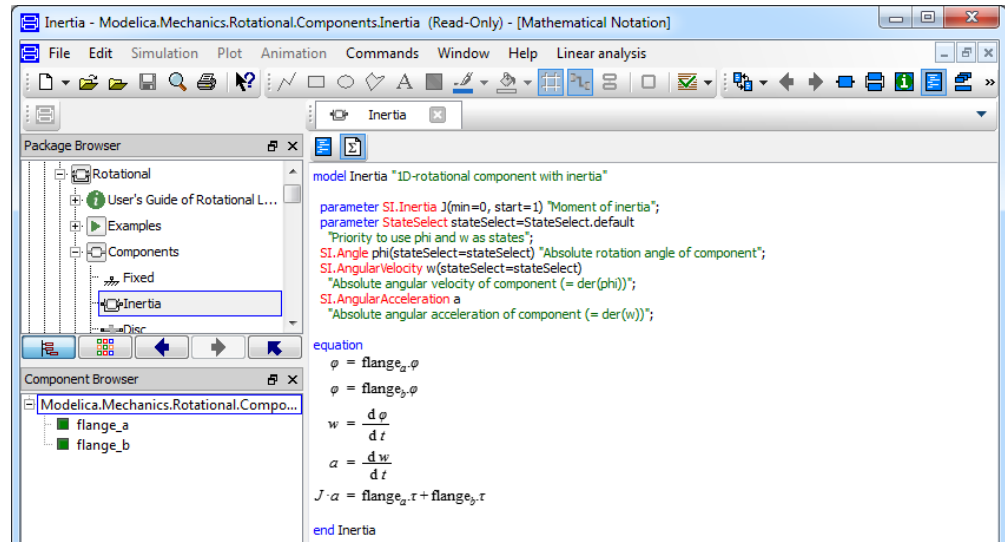

To get a model window for Inertia select **Open Class in New Window** in the same context menu. A window for the model Inertia is created. Switch to the **Modelica Text** representation, where you find Euler's equation as the last equation.

Mathematical definition of a rotational inertia.

If wanted, it is possible to look at the content with equations rendered with mathematical notation. Click the command button **Mathematical Notation** in the toolbar above the Modelica text pane. The result will be:

Displaying using mathematical notation.

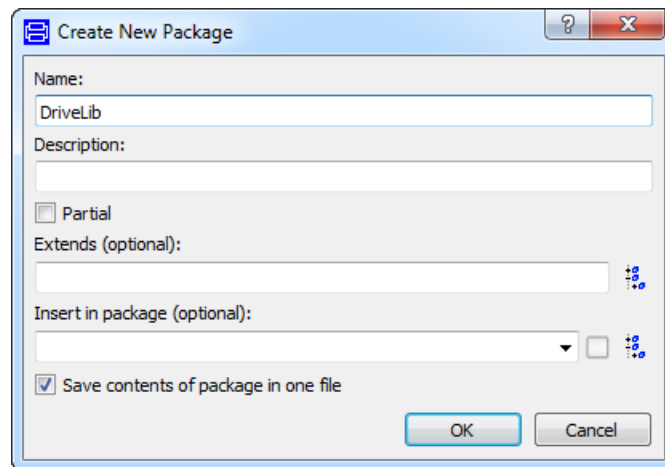

After this introduction of how to access model components and documentation of a library, we will continue by actually building a model for an electric DC motor. This task will give us more experience.

1.4.2 Creating a library for components

It is a good idea to insert developed components into a library. It is a good way to keep track of components and it supports also the drag and drop feature when you will use the models as components. Let us collect all developed components in a library called DriveLib. Go to the Dymola window, and select **File > New... > Package**. This will pop the dialog:

Creating a new Modelica package.

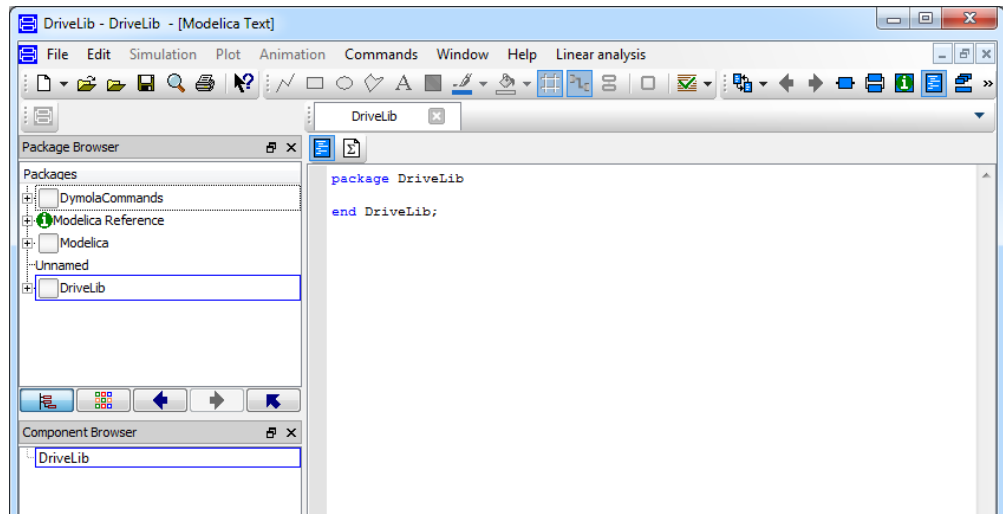

Enter **DriveLib** as the new name of the package and click **OK**, and **Accept** in the information window.

A package DriveLib is created and made visible in the package browser (if scrolled). Select Modelica text to get the Modelica representation, which at this stage just specifies a package with no contents.

The layer shown in the package created (Modelica Text layer, Diagram layer etc) depends on what layer was shown when creating the package. From the result below it is obvious that the Modelica Text layer was shown when this package was created. The layer shown can easily be changed by buttons in the toolbar in the upper right of the window.

DriveLib created.

1.4.3 Creating a model for an electric DC motor

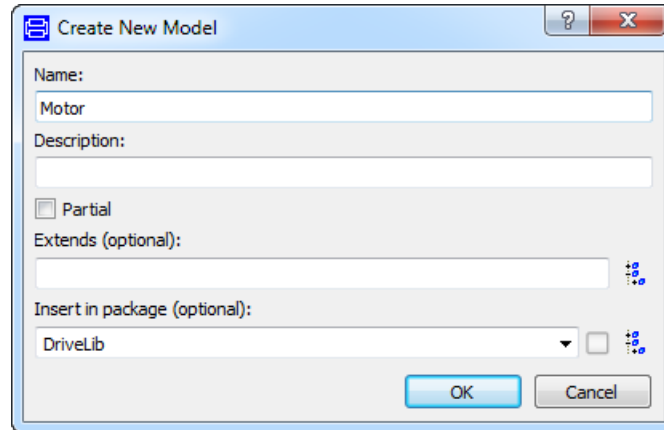

An electrical DC motor.

A model of the complexity indicated above will be developed for the electric DC motor. For simplicity the voltage supply is included in the motor model. The model includes an ideal controlled voltage source. The electric part of the motor model includes armature resistance and armature inductance. The electromotive force (emf) transforms electrical energy into rotational mechanical energy. The mechanical part includes the mechanical inertia of the motor.

Let us start building the motor model. Select in the Dymola window **File > New... > Model**. Enter **Motor** as name of the new model. To have the Motor model being a part of DriveLib, we need to enter **DriveLib** for **Insert in package**. This can be done in several ways. Dymola provides alternatives to be selected from and DriveLib is an available alternative. There are no other alternative because all other open packages are write protected. It is also possible to use the drag and drop feature and drag DriveLib into the slot. In the package browser, put the cursor on DriveLib and press the left mouse button. While keeping it pressed, drag the cursor to the slot for **Insert in package (optional)**, release the button and the text DriveLib will appear in the slot. It is also possible to browse for a package where to insert the model, clicking on the browser symbol to the right.

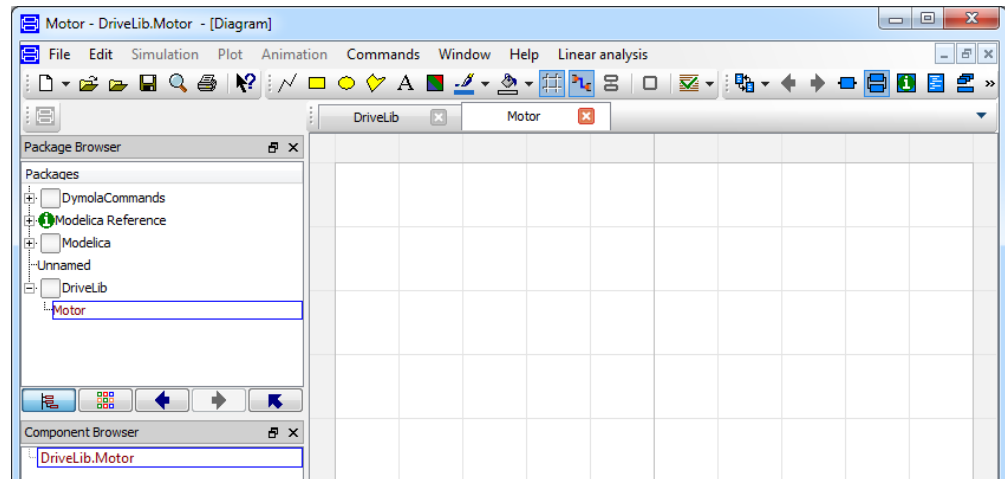

Inserting Motor in DriveLib.

Click **OK**.

The package browser shows that DriveLib has a component Motor as desired. The picture below shows the model with the diagram layer displayed (compare with the package created above).

An empty Motor model.

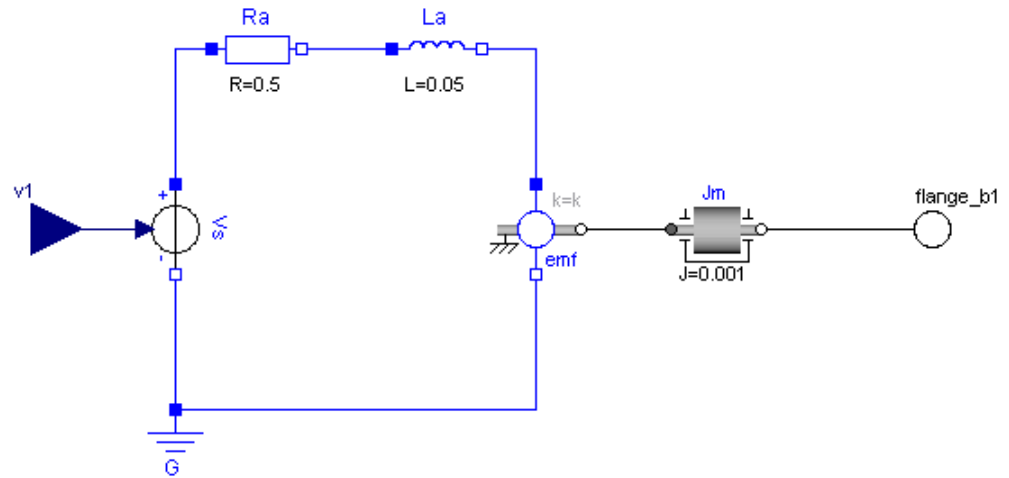

The model window now contains an empty Motor model. The edit window has a gray frame and grid to indicate that the component is not write-protected. It is possible to toggle the grid using the toolbar button.

Before building the motor model, please note that selecting a package in the package browser by just clicking on it does not mean that it is the one that is displayed in the edit window (and component browser). Yes, it is indicated in the package browser by blue (or red if not saved), but the one displayed stays the same (and is indicated by a blue frame in the package browser, the name in the window header, the top name in the component

browser and the name in the bottom left in the window). By *double-clicking* or *right-clicking* on the package in the package browser the displayed package is changed, however.

We will now start building the motor model. To make it easier to follow the instructions, the result is displayed below:

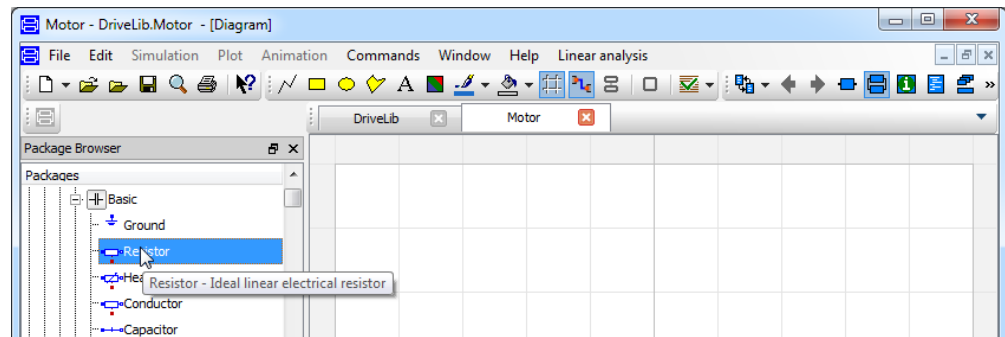

The finished motor model with all components.

We need a model component for a resistor. It can be found in Modelica.Electrical.Analog.Basic. The basic approach is to use drag and drop. You can drag and drop from the package browser or from a library window.

To drag from package browser, open in turn Modelica, Electrical, Analog and Basic. Note that title of the Dymola window is still DriveLib.Motor and also the component browser has DriveLib.Motor as top level to indicate that we are editing the motor model.

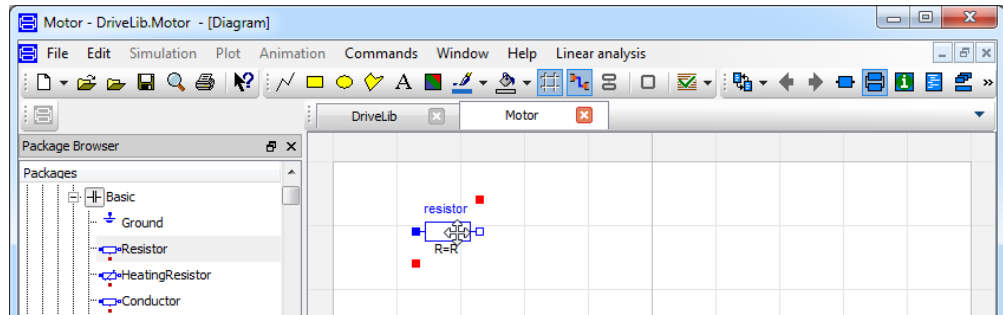

About to drag a resistor from the package browser.

(You can also drag from a library window.)

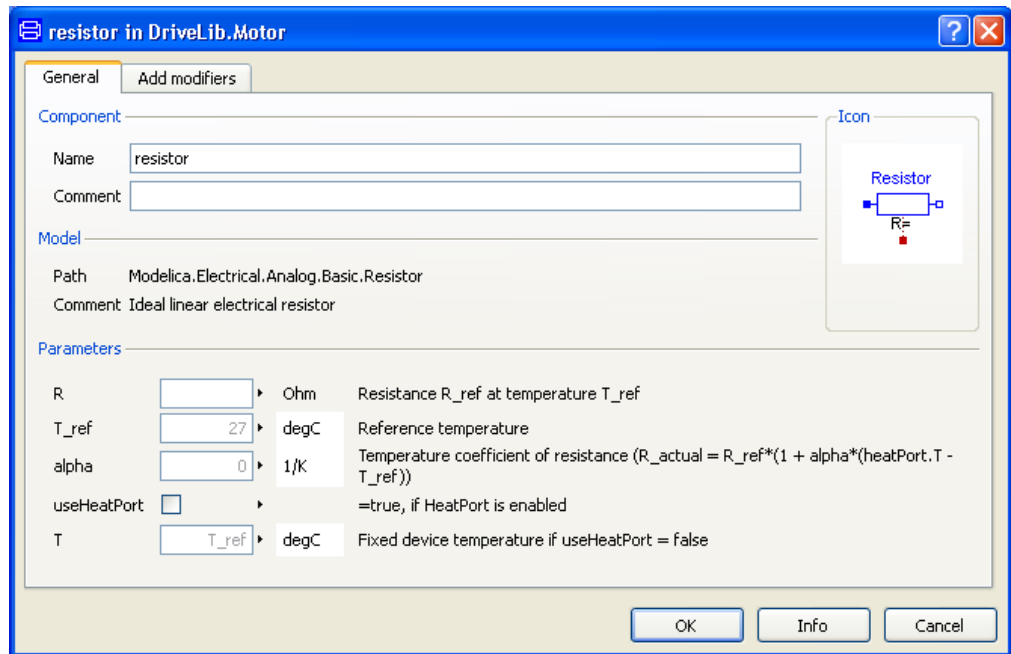

Drag a resistor from Basic to the Motor window and place it as shown above. The component browser displays that Motor has a component Resistor1.

Inserting a resistor component.

When inserting a component it is given an automatically generated name. The name may be changed in the parameter dialog. (The class name begins with an upper-case character, component instances begins with a lower-case character.) Double-click on the component, to get its parameter dialog. The parameter dialog can also be reached by placing the cursor on the component, right-clicking and selecting **Parameters**.

The parameter dialog of a resistor with default settings.

Change the component name to Ra. The parameter dialog allows setting of parameter values. To set the resistance parameter, R, select the value field of parameter R and input 0.5.

The parameter dialog of a resistor with new settings.

Click **OK**.

Similarly drag an inductor to the Motor window. Name it **La** and set the inductance, **L**, to 0.05.

Drag a ground component into the motor model. Name it **G**. The ground component is as important as in real electrical circuits. It defines the electrical potential to be zero at its connection point. As in the real world, never forget to ground an electrical circuit.

Drag an electromotive force, EMF, component into the motor model. Keep the name **emf**. (The component is grounded, meaning that the component has a support, where the support connector is fixed to the ground. Please keep in mind the difference from electrical grounding.)

A voltage source is to be found in Modelica.Electrical.Analog.Sources. Use a library window or package browser to locate it. Select SignalVoltage and drag it to the model window of Motor. Name it **Vs**. Let **Vs** be selected and use **Edit > Rotate 90** to turn the signal input, **Vs.inPort**, from a top position to a left position.

SignalVoltage produces, between its two electrical pins, **p** and **n**, a voltage difference, **p.v-n.v**, that is equal to the signal input. (This info can be displayed by right-clicking on the icon and selecting **Info**). To get the proper sign we would like to have pin **p** in the top position. Since the pin **p** (“+”) is the filled blue square, we must flip the component. To do that, use **Edit > Flip Vertical**.

A rotating inertia component is to be found in Modelica.Mechanics.Rotational.Components. Drag and drop such an inertia component. Name it **Jm** and set the inertia parameter, **J**, to 0.001.

Now all model components are in place. Components are connected by drawing connections between connectors. Connect the resistor to the inductor by pointing at the right connector of the resistor (the small white square), press the left mouse button and keep it pressed while dragging it to the left connector of the inductor. The resistor and the inductor are now connected and the graphical result is a line between them. When connecting the voltage source and the resistor, break the line by clicking at an intermediate point. There is a possibility to obtain automatic Manhattanize of connections (non-endpoints of the connections are moved to make all line segments horizontal or vertical). Select the connection, right-click and select **Edit > Manhattanize**. Draw all connections. Note that we could have drawn a connection between two components as soon as we have the components and we have not to wait until all model components are in place. The points of the connectors can be moved, and new points can be inserted using the context menu of the connector.

Finally, we have to introduce a signal connector for the voltage control and a flange connector corresponding to the shaft of the motor so the motor can be connected to an environment. We would like to place the icon of the connectors at the border of the grid of the drawing pane, because the icon of a model component also includes the connectors. The connector inPort must be compatible with the connector of Vs.inPort. There is a simple way to get a connector inPort that is a clone of Vs.inPort. Start drawing a connection from Vs.inPort and go to the left until you reach the border of the grid. Then you double-click and select **Create Connector** from the menu popped up. The connector flange_b is created in a similar way. If you would like to adjust the position of a connector it is easy to get into connect mode. This can be avoided by toggling the toolbar button **Toggle Connect Mode** (when the background is white it is in connect mode).

Click on **Icon** toolbar button to look at the icon layer. You will see the icons for the connectors. Let us draw an icon for the motor model. One design is shown below. (The thicker line to the right symbolizes the physical axis from the motor. It is a good idea to select that line and use the context menu **Order > Send to Back** to prevent any case where the axis seems to be lying outside the motor.)

The icon of the electrical DC motor.

To draw it, we will use the toolbar for editing graphics.

Toolbar for editing.

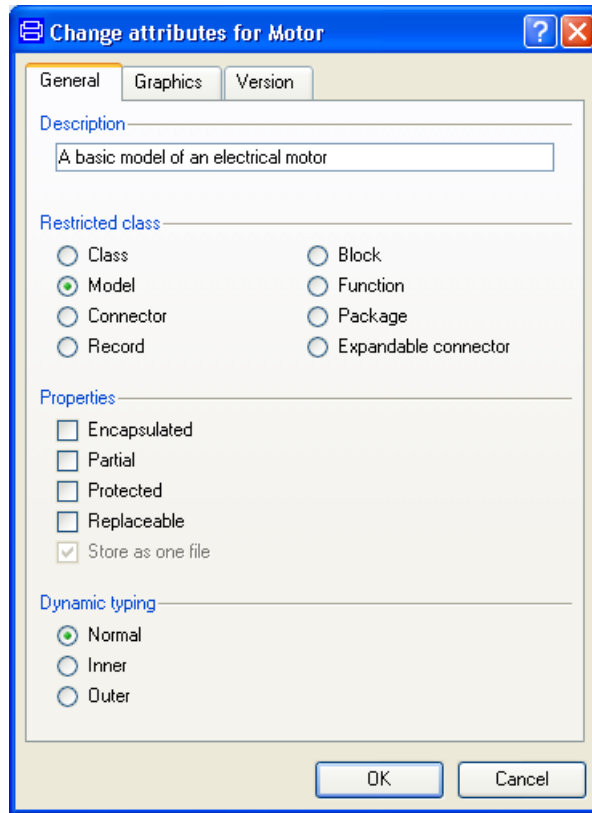

Start by drawing the big red cylinder (shaded rectangle); Click the **Rectangle** button (yellow rectangle) and draw a rectangle. Let it be selected. Click on the arrow to the right of the **Fill style** button. Select **Colors...** and then select a red color. Click **OK**. To select the gradient, click once again on the arrow to the right of the **Fill style** button. Select **Gradient > Horizontal**. Draw the rest of the parts using **Rectangle** or **Polygon** in an analogous way. To enter the text, click the **Text** button (the button labeled A) and lay out a rectangle that is as long as the cylinder and one grid squares high. In the window prompt for the string enter `%name` and click **OK**. The % sign has the magic function that when the model is used, the actual component name will be displayed.

1.4.4 Documenting the model

We have now edited the icon and the diagram. It is also important to document the model. When creating the model, the dialog has a slot **Description**. It is possible to edit this afterwards. Select **Edit > Attributes...** to open the dialog.

Model attributes.

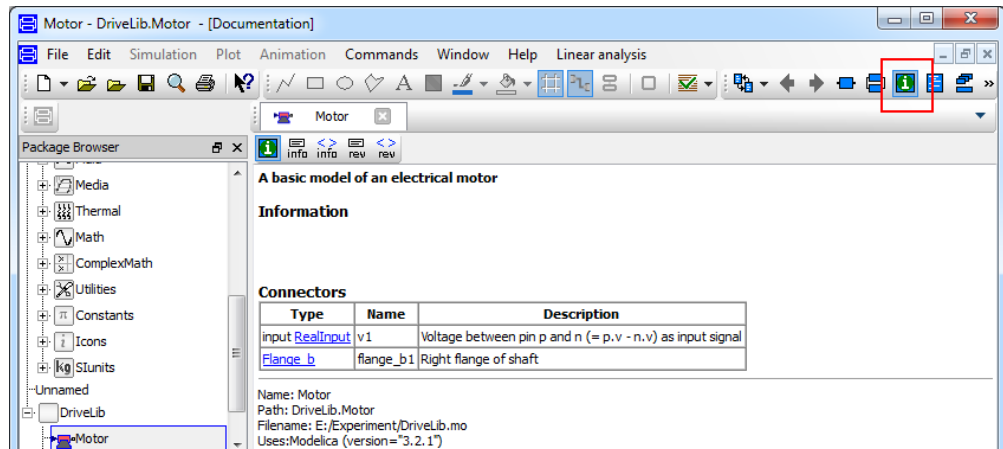

Enter a description and click **OK**.

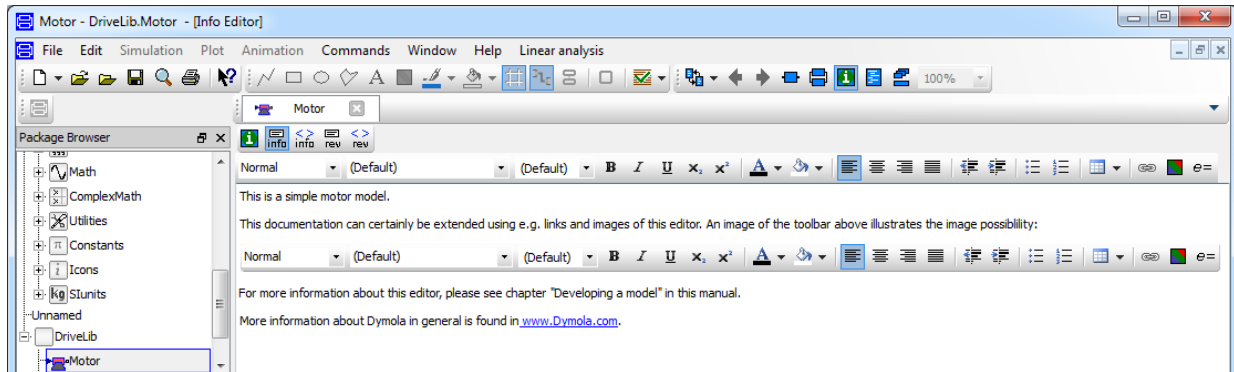

Documentation View.

A longer documentation can be provided in the following way. Click on the toolbar button for **Documentation** (the button between the Diagram button and the Modelica Text button).

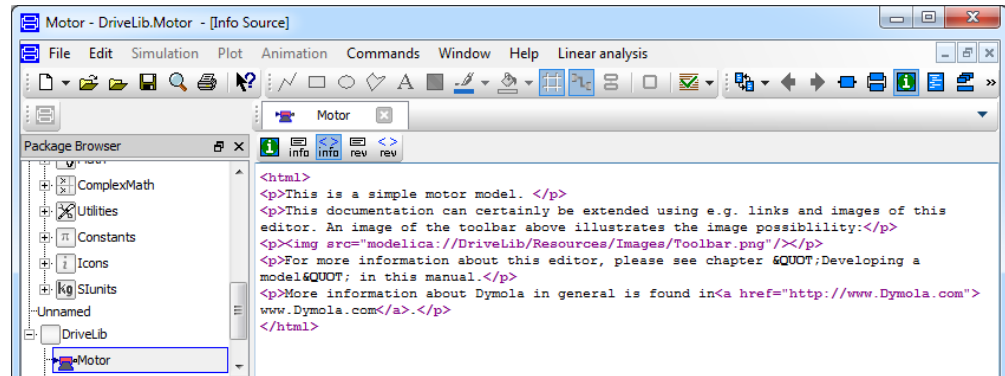

Documentation editor.

To enter a description, click the command button **Info Editor**  in the toolbar on top of the documentation layer. You now have access to a documentation editor for the model/class with text-editing possibilities as well as link creation and image insertion. After insertion of some text, an image and a link the result can look like:

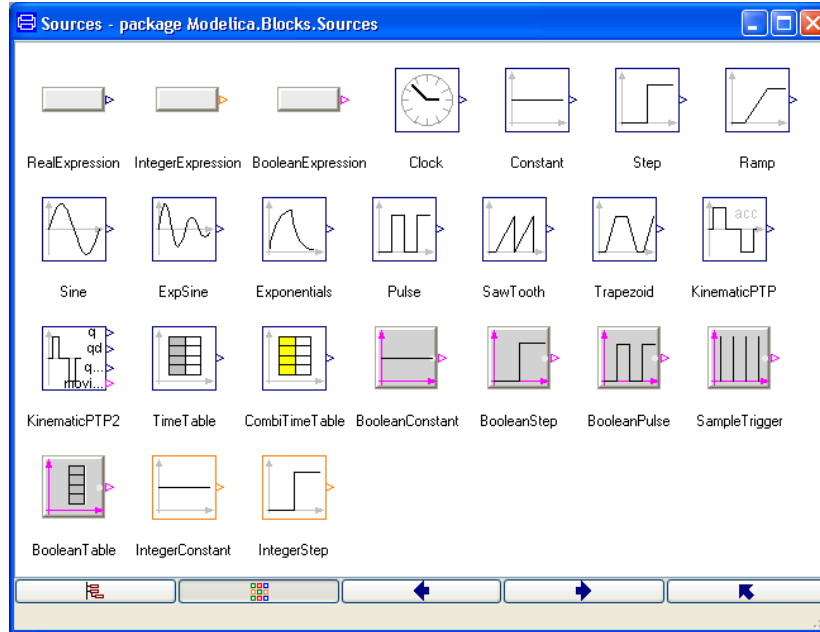

The created source code in html formatting can be viewed clicking **Info Source**  in the toolbar on top of the documentation layer.

The corresponding html source code.

It is important to test all models carefully, because that eliminates tedious debugging later on. Let us connect the motor to a voltage source. Create a model called TestMotor and insert it into DriveLib. The easiest way is to use the command **File > New... > Model**. It is good practice to keep testing models. Drag a Motor component from the package browser into the diagram layer of TestMotor. We need a source for the signal input to the motor. Signal sources are to be found in Modelica.Blocks.Sources.

Signal sources.

Drag, for example, over Step to the model window and connect it to the motor.

Now it is time to simulate. Click on the tab for **Simulation**. This will change the *mode* from Modeling mode to Simulation mode. To simulate *the model* click on the toolbar button **Simulate**. (Please note the difference.)

Some warnings will be presented. Please see next section on how to get rid of them. However, they are warnings, so the simulation will work anyway.

To inspect the result, we will first look at the angular position of the motor, motor.flange_b.phi. Open motor in the variable browser by clicking on the + sign. Open the flange_b and tick phi.

Angular position.

First, we may establish that a positive input signal makes angular position increase. The plot looks almost like a straight line. However, there are some wriggles in the beginning. Zoom in; use the mouse to stretch a rectangle over that portion of the curve you would like to see. We may also plot the angular velocity `motor.Jm.w`; there is an oscillation which dies out and the velocity becomes constant. There is much to be done to validate the model. However, model validation is out of the scope for this introduction to Dymola.

It is possible to show several curves in the same diagram. Simply tick the variables to be plotted. A curve is erased by ticking once more. The toolbar button **Erase Curves** (white rectangle) erases all curves in the active diagram. It is also possible to have several diagrams. To get a new diagram, select **Plot > New Diagram** or click on the toolbar button. The new diagram becomes active. Selecting a diagram makes it active. (Selecting **Plot > Delete Diagram** removes the diagram.)

(In addition to the above, there are numerous options in the plot window, e.g. you can

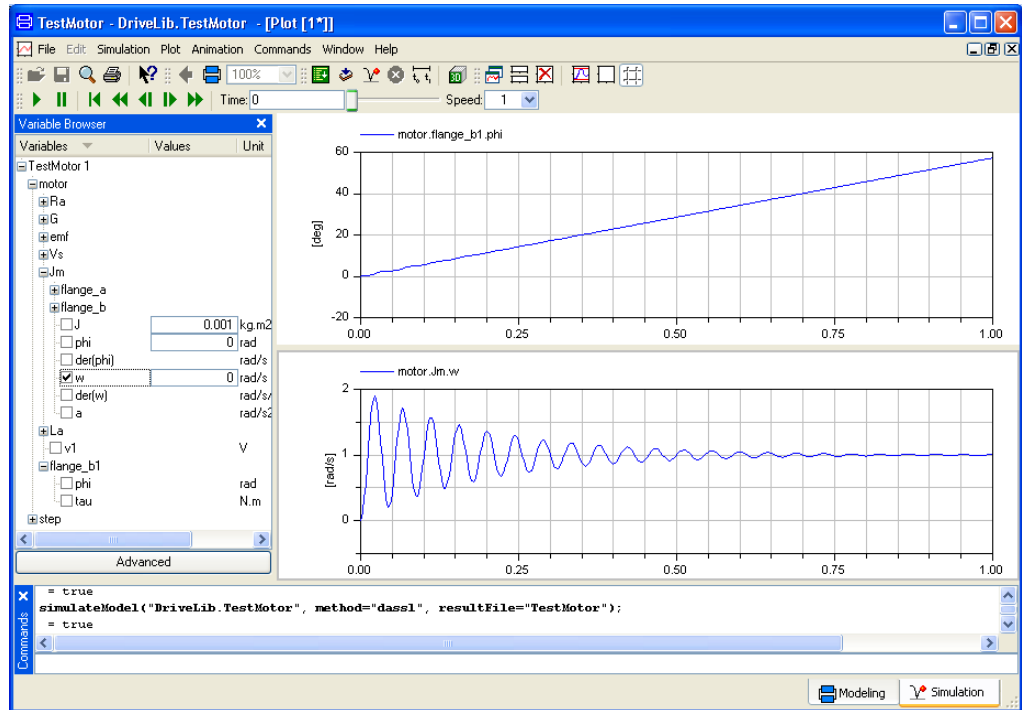

- Display dynamic tooltips (and copy the values to clipboard if needed).
- Display tooltip for the legend to see more information about the corresponding signal.
- Display tooltip for the x-axis and the y-axis.
- Moving and zooming (one way of zooming is to just drag a rectangle over the area that is of interest).

- Change time unit on x-axis.
- Change the display unit of a signal.
- Display signal operators.
- Plot general expressions.
- Plot dependencies.
- Select multiple curves in a diagram (for e.g. copying the curve values to Excel).
- Display a table instead of curves, or create tables from curves.
- Plot parametric curves.
- Display Boolean and enumeration signals.
- Change color, line/marker style and thickness of a signal.
- Set diagram headings and axis titles and ranges.
- Insert and edit text objects in the plot.
- Change the appearance, layout and location of the legend.
- Display the component where the signal comes from in a new window containing the diagram layer.
- Go back to a previously displayed plot window (or any other window previously displayed.)

For more information about these options, please see chapter “Simulating a model”.)

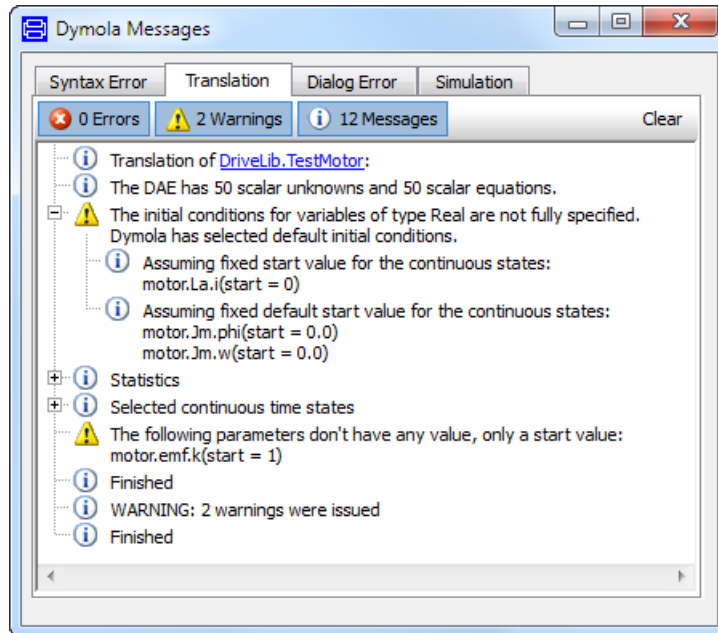

Using the option of adding a new diagram and ticking `motor.jm.w` the result shown below is obtained.

Angular velocity.

1.4.6 Handling the warnings

When simulating the TestMotor, warnings can be seen by looking at the Translation tab of the Message window (you have to expand the first warning to see the submessages of that warning):

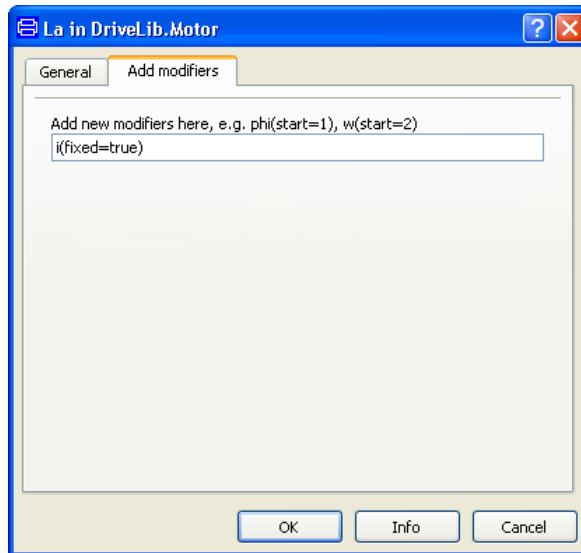

Two types of warnings are present for this example; a warning that initial conditions are not fully specified (at the top of the tab) and a warning that a parameter does not have any value, only a start value (at the bottom of the tab).

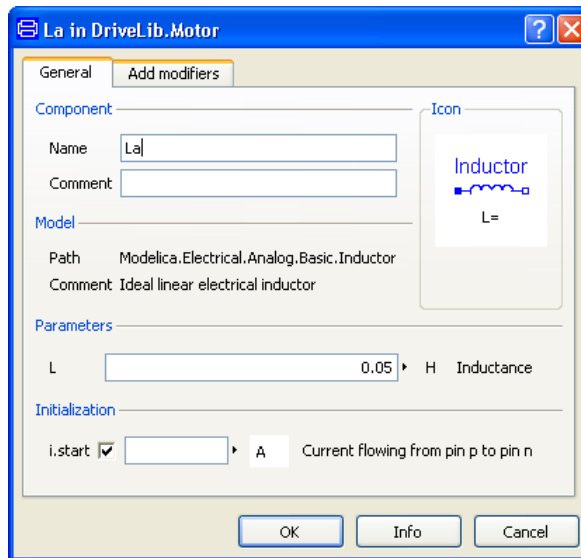

The first type of warning has been described previously, see section “Handling of warnings” on page 35. The difference here is that we can use the graphical user interface to set the variables to fixed; we do not have to enter code.

Looking at the warnings, they all have to do with components inside the Motor model. By double-clicking on the Motor in the package browser we return to this model.

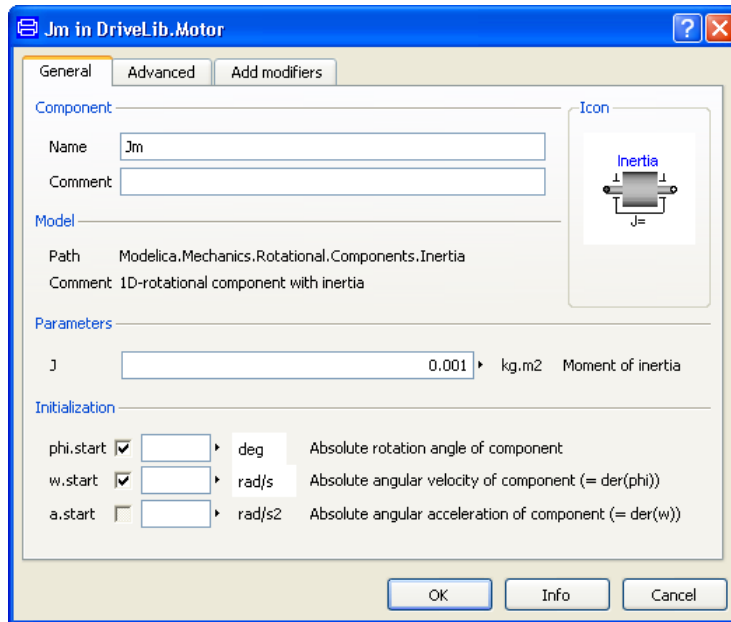

The first variable of the upper warning section is located in the inductance component La. Double-clicking on this component will however not display any Initialization section. But since the variable is known, we can click on the tab **Add modifiers** and enter the text `i(fixed=true)` and press **OK**.

When having clicked **OK**, the General tab will change to present the new initialization information. Double-clicking again on the inductance component will result in:

The two last warnings in this part have to do with the inertia J_m . Double-clicking on this component brings up the parameter dialog for it, and in the Initialization section ϕ and w are found. By clicking on the little square in front of each of these variables, a menu pops where we can select `fixed=true`. The final result will be:

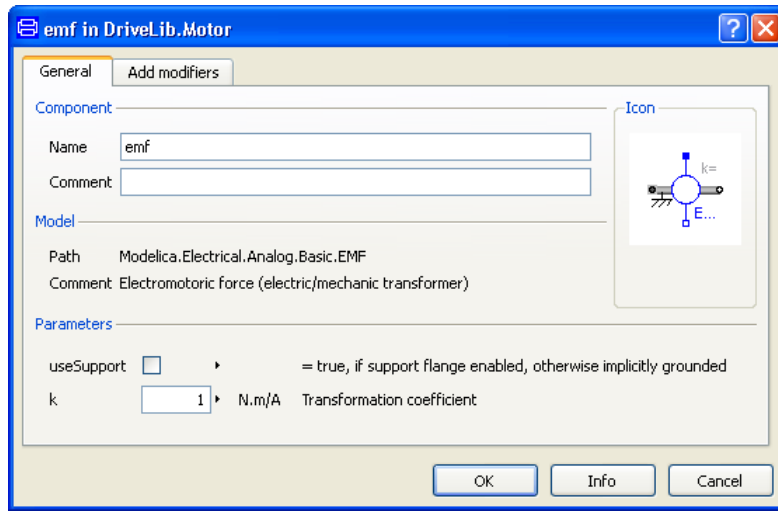

Click **OK** to confirm the changes.

If simulated again, the upper warnings in the Translation tab will not be present any more.

The lower warning states that the parameter `motor.emf.k(start=1)` only has a start value (`start=1`) but no value.

The warning implies that this parameter value is generic and that it ought to be set by the user. (More about such warnings can be read in chapter “Developing a model”, section “Advanced model editing”, sub-section Parameters, variables and constants”.)

The way to handle this is to double-click on the emf component and set the value of `k` to 1.

Click **OK** to confirm the change.

When simulating again, no warnings will be given.

1.4.7 Creating a model for the motor drive

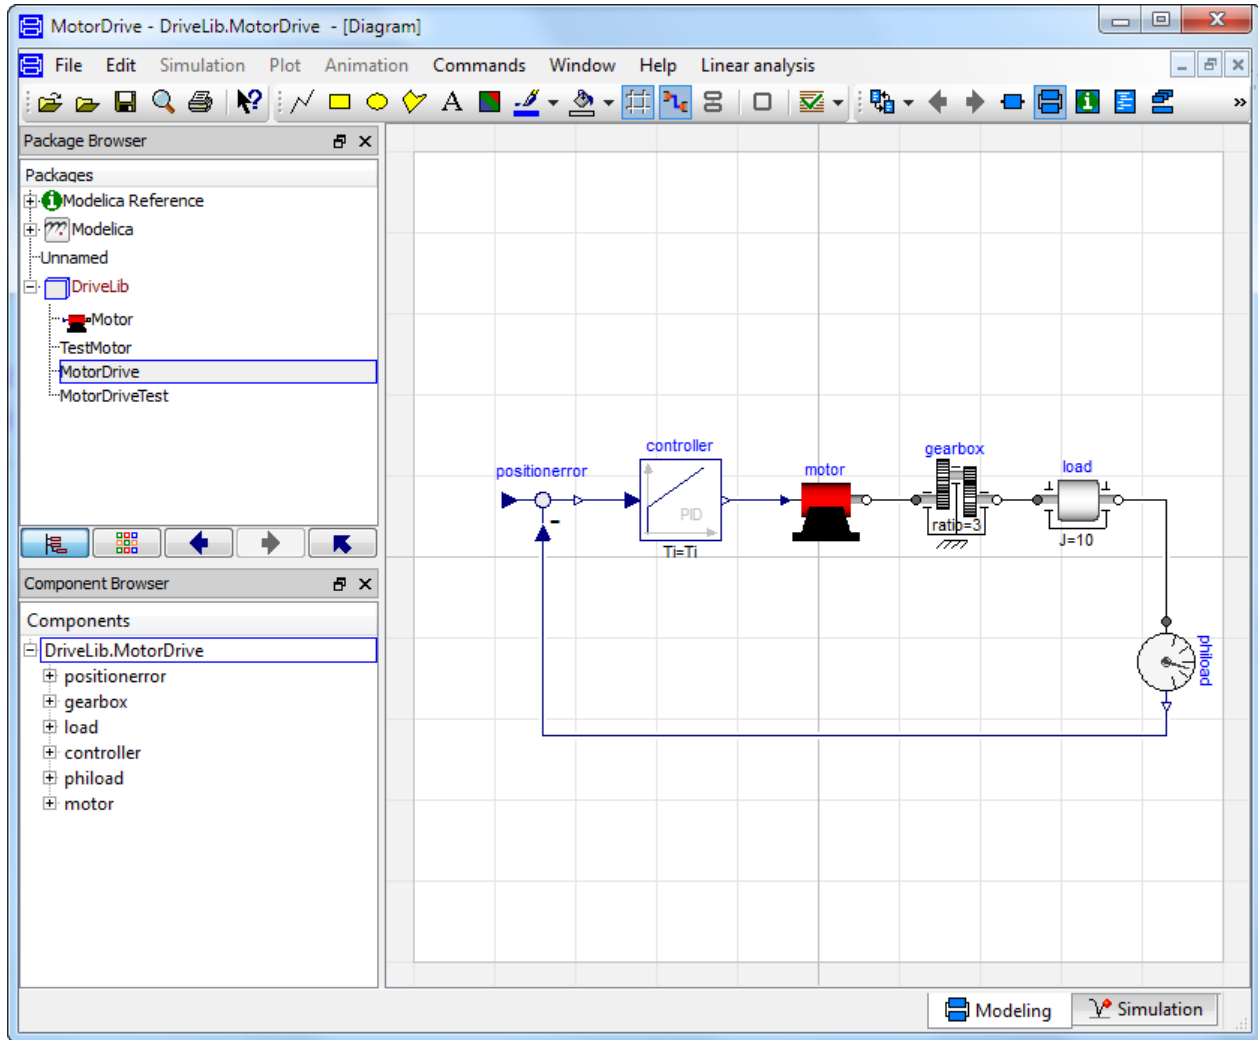

The task was to build a model for a motor drive and it ought now to be a simple task to complete the model. We will just give a few hints. Note that the full names of the components are given in the component browser at the lower left.

Give the model the name MotorDrive – we will refer to that name later on. Put it in DriveLib.

To generate the position error, you may use the model component Modelica.Blocks.Math.Feedback. For the controller, there is Modelica.Blocks.Continuous.PID.

In this simple example we can select the component Modelica.Mechanics.Rotational.Components.IdealGear as gearbox. For the meaning of ratio for the gearbox model please consult **Info** for the model. Set ratio to 3 as indicated. It means that the motor load rotates 3 times slower than the DC motor. The library Modelica.Mechanics.Rotational.Sensors contains a sensor for angles.

Inserting a load was dealt with when building the motor model.

To test the model `MotorDrive` for normal operation, we need to define a reference for the position. This can be done in different ways. A simple approach is to add a signal source directly to `MotorDrive`. However, we may like to use `MotorDrive` also for other purposes. If we would like to use the drive as a component we could add a connector for the reference as we did for the electric DC motor model. However, here we will take the opportunity to show another useful way, namely use of extends. We will develop a new class, say `MotorDriveTest`, which extends `MotorDrive`. Select `MotorDrive` in the package browser and select **Edit > Extend From...** in the context menu. This gives the same dialog as **File > New... > Model**, but with several fields filled out. (It extends from `MotorDrive` and is inserted in the same package, `DriveLib`.) Enter `MotorDriveTest` as the name of the model. Click **OK**. The result is a model window, where the diagram layer looks exactly like that of `MotorDrive`.

However, the components cannot be edited. Try to move or delete a component. It has no effect. Drag a component Step from Modelica.Blocks.Sources to the edit window and connect it. Save the model.

(It is valuable to give some thoughts comparing “extend” to “copy/paste+add”. The former strategy allows a far more clean structure, where an object can be reused in a number of locations. If that object is further refined, all objects extended from that one will gain from that refinement.)

A model can be used for different tasks. One is tuning the controller manually. Click on the tab for **Simulation**. Translate the model MotorDriveTest by clicking on the **Translate** button. (Also delete one of the plot windows and delete the previous curve.) The PID controller has four parameters: k, Ti, Td and Nd.

(There will be some warnings when translating. We will take care of those later.)

One way to tune a PID-controller is by first disabling the integrator and derivative parts. This is achieved by setting a large value for Ti and a small value for Td. Set $k=2$, $T_i=1000$, and $T_d=0.001$ and simulate for 5 seconds. (Use **Simulation > Setup...** to change the stop time.) As can be observed, the step response is very slow. Increase k to find out what happens. Make sure to also investigate the magnitude of the control signal, controller.y. The result will be:

Tuning the controller.

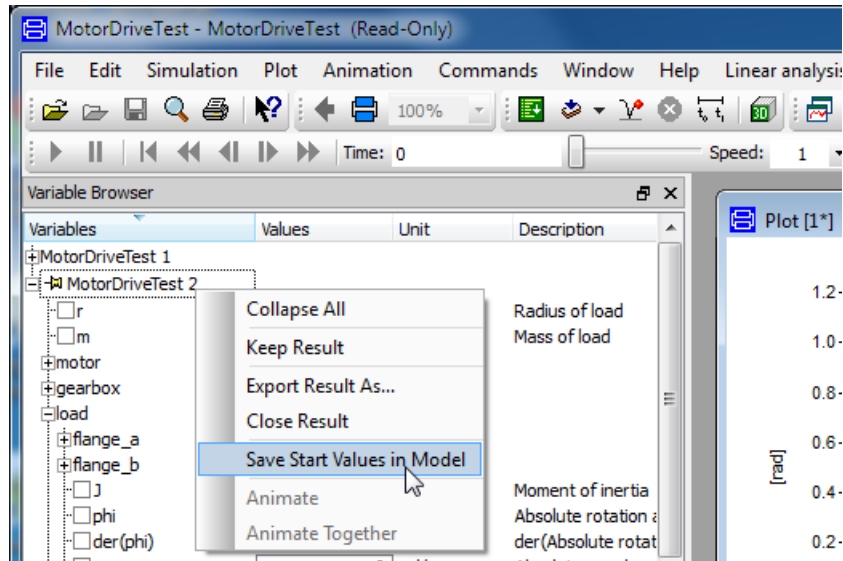

The interested reader may next proceed to tune the controller parameters to obtain a nice step response. For example, aim at a rise time around 0.4 seconds, a settling time around 1 second, maximum overshoot of 10 percent, and a maximum control signal magnitude of 100. Enforce the last constraint by adding a `Modelica.Blocks.Nonlinear.Limiter` component between the controller and the motor in the `MotorDrive` model. Set `uMax=100` and `uMin=-100` for the limiter. (We will not show this component in the code.) The result might be something like:

Tuning result.

Saving changed start values to the model

Having tuned values in simulation mode like the interested reader above, it is a big advantage to be able to directly save them in the model (changing the Modelica code). This can be done by right-clicking on the result file in the variable browser and selecting **Save Start Values in Model** like below (on purpose the wanted values are hidden under the menu, not to destroy the challenge of finding better values in previous section):

Handling the warnings

There will be some warnings when translating. The principal handling of these warning has been dealt with previously. The only thing that ought to be mentioned here is that in order to make the variable `controller.D.x(start=controller.D.x_start)` fixed, you have to double click on the MotorDrive, then select the controller, right-click and select **Show component**. Now you can double-click on the D component to see the parameter dialog, and since no `x` is available you have to select the **Add modifier** tab, enter `x(fixed=true)` and press **OK**.

The rest of the warnings can be handled like described in a previous section.

1.4.8 Parameter expressions

Modelica supports parameter propagation and parameter expressions, which means that a parameter can be expressed in terms of others. Assume that the load is a homogeneous cylinder rotating long its axis and we would to have its mass, m , and radius, r , as primary parameters on the top level. The inertia is

$$J = 0.5 * m * r^2$$

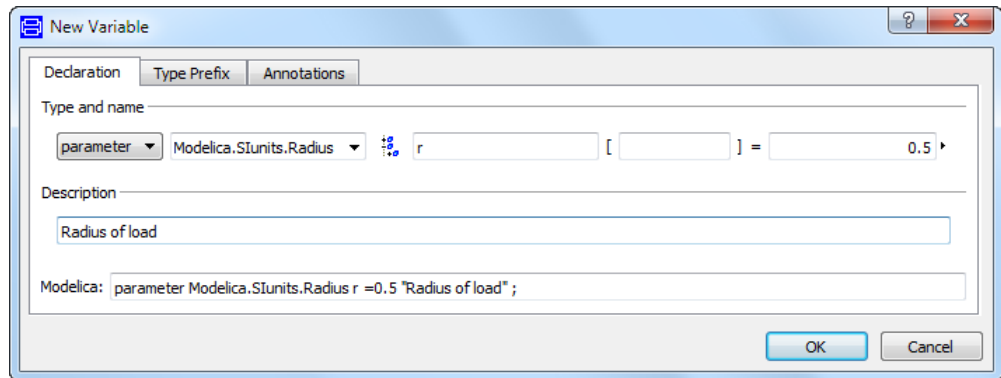

We need to declare m and r in MotorDrive. Open MotorDrive. Activate the Modelica Text representation; press the **Modelica Text** toolbar button (the second rightmost tool button).

The parameters and variables are more than real numbers. They are physical quantities. The Modelica standard library provides type declarations for many physical quantities. *Select* Open Modelica.SIunits by clicking on it in the package browser (note, do not open it; MotorDrive should still be open). For the parameter r , which is a radius, it is natural to declare it as being of type Radius. To find it enter r and the browser goes to the first component starting with r/R . If it is not the desired one, press r once again and so on to find it.

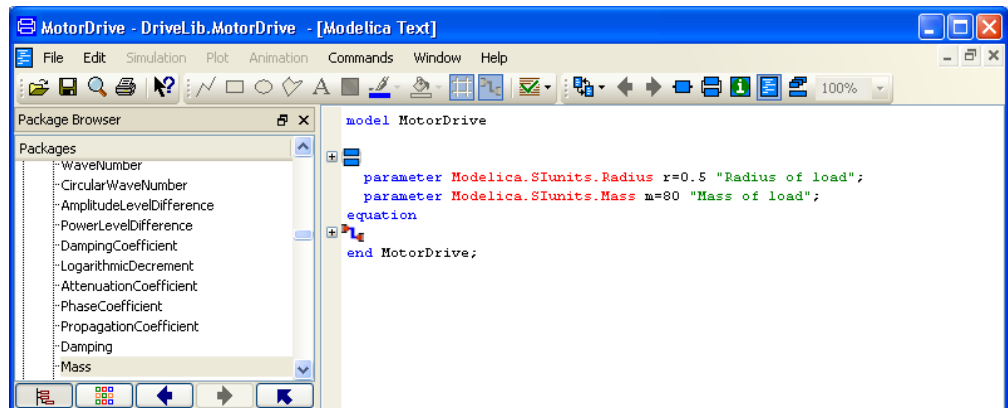

When you have found Radius, drag it to the component browser below. The choice to add a component is pre-selected. Click **OK**. A menu to declare a variable pops up. Complete the declaration (do not forget to change to a parameter):

Declaration of parameter r.

Click **OK** and the text appearing in the bottom row is inserted into the Modelica text window. The parameter m (being 80 kg if the resulting inertia should be the same as previously) is defined in an analogue way.

Parameter declarations added to motor drive.

In Modelica Text representation above, the components and connections are indicated by “+” in the margin to the left of the text, and icons in the text. It is possible have them expanded textually in two ways.

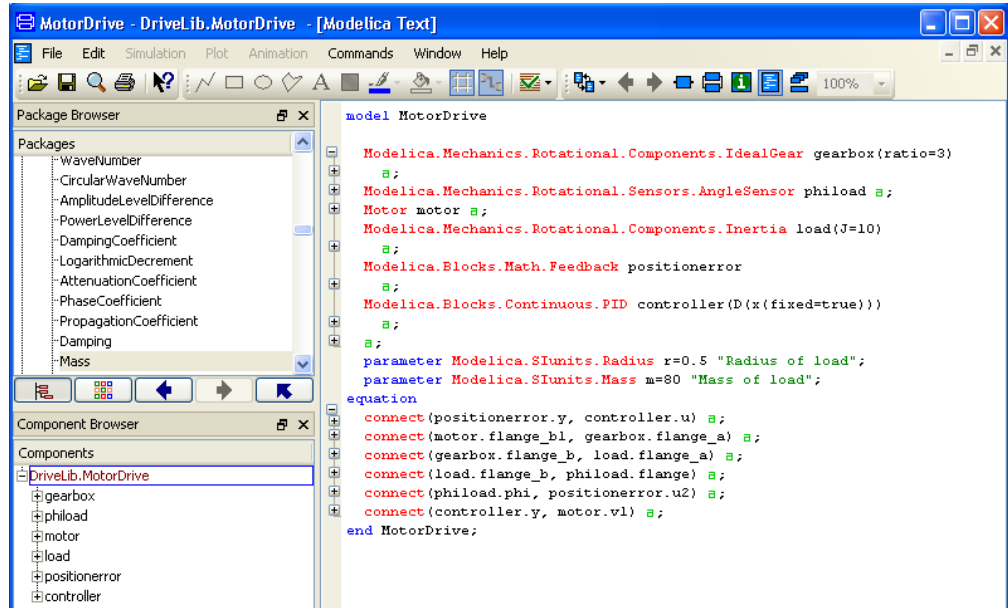

One way is to work with individual annotation. It is possible to click on the “+” or the corresponding icon to expand that annotation but no other. If “sub-annotations” are present, new “+” and icons will be visible, which in turn can be expanded. (Of course they can also be compressed using “-“.)

The other way is to work with all annotations at the same time. If that is wanted, right-click and select **Expand > Show components and connect**. It is also possible to expand the annotations such as the graphics for the icon of the model, the positions and sizes of the icons of the components, the path of the connections etc. This is done by right-clicking and

selecting **Expand > Show entire text**. However, we refrain from showing it in this document.

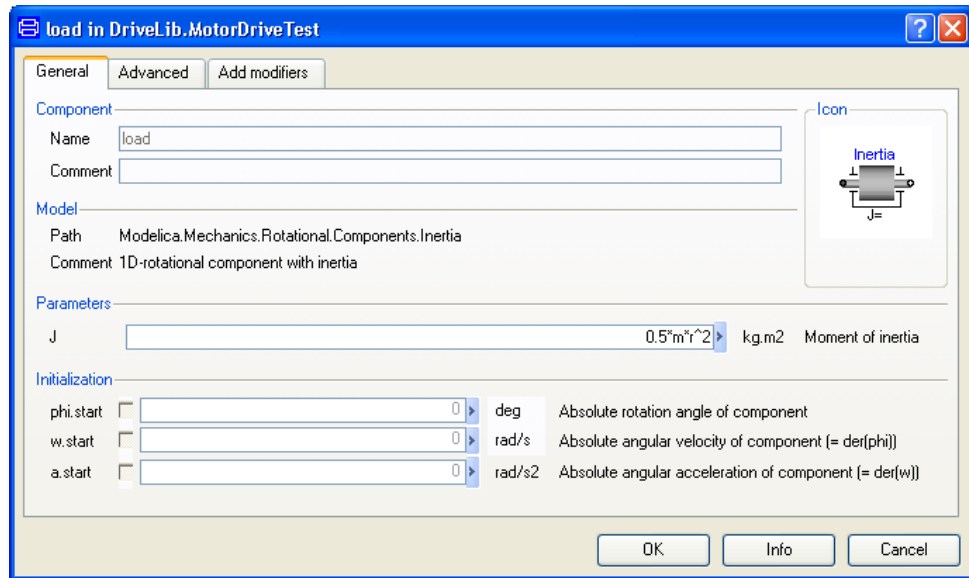

Below the Modelica text as a result of first selecting select **Expand > Show components and connect** and then the annotation for Motor has been individually expanded by clicking on a corresponding “+” in the margin (which means that now a “-“ is shown, indicating the possibility to compress that annotation individually).

Expanded text representation.

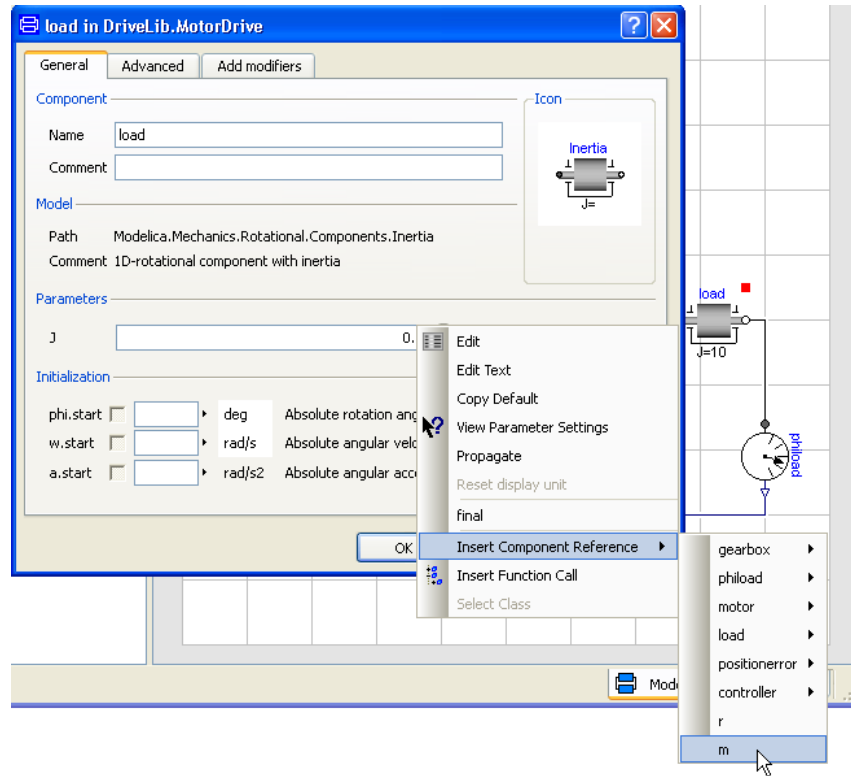

Ok, now activate the diagram representation. Double-click on the load icon to open the parameter dialog.

Binding a parameter to an expression.

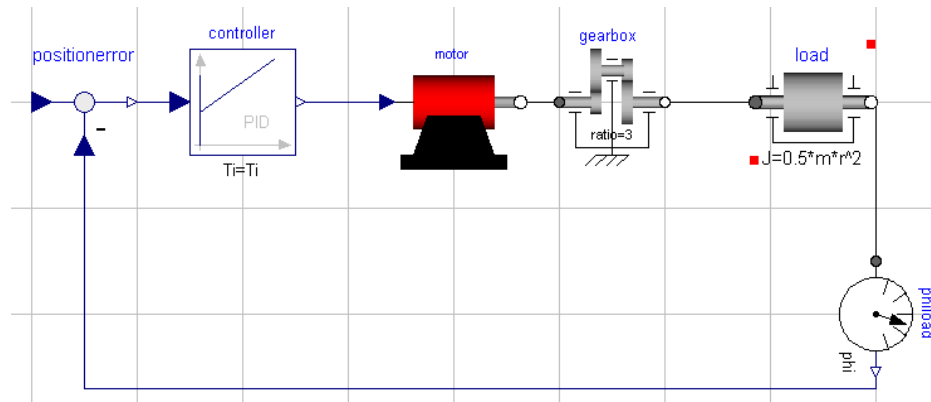

Click in the value field of J and enter the expression for J. Click **OK**. The model window now displays the expression for the load inertia. When entering the expression, you are sometimes not sure about the exact name of the variables names, for example is the radius called r, r0 or r1? The problem is even more pronounced when you would like to reference a variable a bit down in the component hierarchy. Dymola can assist you. First you enter 0.5* and then you click on the small triangle to the right of the value field. Select **Insert Component Reference** and then **m**.

Using Component Reference to enter a formula.

You have now $0.5*m$ in the value field for J . Enter $*$. Use the menus to get a reference to r . Complete the expression with the square. Click **OK**. The model window now displays the expression for the load inertia.

The component's parameter definition is visible in the model.

Open MotorDriveTest and switch to Simulation mode.

Translate.

A bound parameter cannot be changed interactively.

The parameters `r` and `m` can be set interactively between simulation runs, but not the parameter `load`. Because it is no longer a free parameter; an expression is now binding it to `r` and `m`.

1.4.9 Documenting the simulation

The command window can be used to document the simulation. Text (also headers), images, links, and mathematical expressions can be inserted and edited using the tools that are available in the toolbar in the top of the command window.

Plot results can also be inserted in the command log (together with the corresponding plot command) by using the context command **Show In > Command Window**. (Note that you must not right-click on a curve etc., but in an empty area of the window, to get the general context menu.)

Now the content in the command log pane can be edited to document the simulation in a good way. Commands given and output results will be automatically be included.

An example of documenting better values of the PID controller could be:

Some comments:

- This example is just a minor example of what can be done. More about using the command log pane to document simulations can be read in chapter “Simulating a model” in the manual. Note that math rendering of equations etc. is supported, including indexing and Greek letters.
- The command log pane is enlarged; the command window can also be undocked instead using the **Undock** button.
- The header and the last line are entered by the user.
- The simulation command is output from the system: including “true” in the following line, indicating success (assuming the user has given a simulate command).

- The plot command and plot image are added the following way:
 - The variables are plotted in a plot window.
 - To get the plot command in the plot window (really not needed for documentation, but for scripting), the user clicked the command input line of the command window – that echoed the underlying plot command in the command log.
 - To add the image, the user right-clicked an empty space in the plot window, and selected **Show In > Command Window**.
 - The user removed the rather long createPlot command that was added together with the image.
- The content of an animation window can also be included using a flag; the below shows how to set this flag to true by typing in the command input line of the command window. This is a typical example of setting a flag; using flags is not unusual in Dymola.

- Sections of the command log pane can of course be copied to e.g. Microsoft Word for further work.
- The content of the command log pane can be saved as a command log in Dymola, in various formats (and including various contents).

1.4.10 Scripting

Scripting makes it possible to store actions, for various reasons. Examples might be:

- The script can be used to run a demo.
- The script can be used for testing of e.g. different parameter sets.
- The script can be used as an action that can be included in other models.

The first item can be solved creating a script file; while the last one is best solved creating a function that can be included in other models.

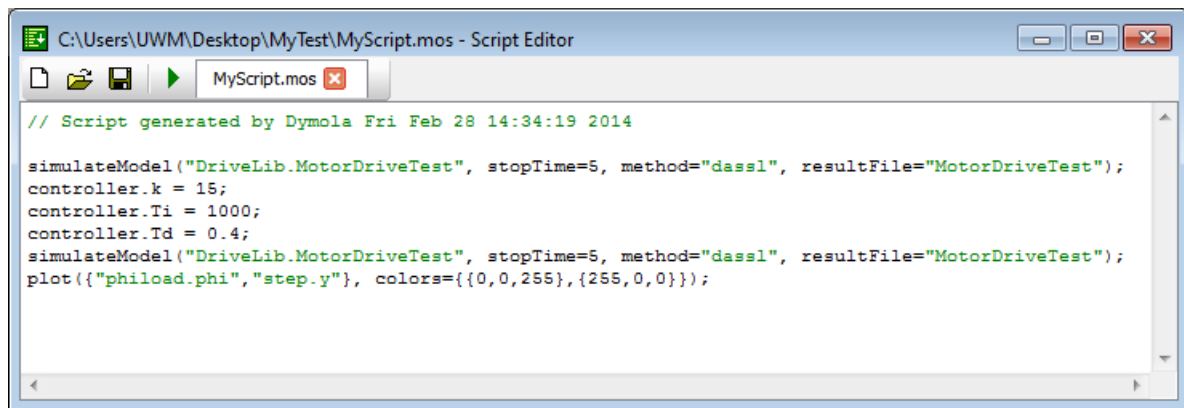

Creating functions is not treated here, please see chapter “Simulating a model” in the manual for more about scripting, in particular using functions.

If the simple example here should be saved as a script file, the easiest way is to do the following (assuming that the models have been saved):

1. Go to Modeling mode, clear everything using the command **File > Clear All**.
2. Clear the content of the command log pane using the command **File > Clear Log**.
3. Reopen the DriveLib package using **File > Recent Files**.

4. Open MotorDriveTest, and simulate it.
5. Set wanted values of controller. Simulate again.
6. Plot `phiload.phi` and `step.y`. (If those are already selected, you may have to deselect them and select them again to get the below item to work.)
7. Force a plot command in the log by clicking the command input line.
8. Save the command log using **File > Save Log...** Select saving it as a Modelica Scripts (*.mos) file by selecting that alternative in the **Save as type** input field. Save the script where the model resides. Give it a name, e.g. MyScript.

The saved script can be opened (and edited) using the Dymola script editor. (A general text editor, e.g. Microsoft Notepad can also be used, but the script editor contains more facilities.)

The screenshot shows a window titled "C:\Users\UWM\Desktop\MyTest\MyScript.mos - Script Editor". The window contains the following text:

```
// Script generated by Dymola Fri Feb 28 14:34:19 2014

simulateModel("DriveLib.MotorDriveTest", stopTime=5, method="dassl", resultFile="MotorDriveTest");
controller.k = 15;
controller.Ti = 1000;
controller.Td = 0.4;
simulateModel("DriveLib.MotorDriveTest", stopTime=5, method="dassl", resultFile="MotorDriveTest");
plot({"phiload.phi", "step.y"}, colors={{0,0,255},{255,0,0}});
```

Note the difference between the saved log and the content in the command log pane. By saving as a .mos file *only* executable commands are saved.

Note also that the plot command echoed in the command log does not include features like plot header etc.; but for simple plot handling this is sufficient – more advanced commands can be used to fully restore a plot window using scripting.

To run the script, you have to be in Simulation mode. The command **Simulation > Script > Run Script...** (or corresponding command button) can be used to open (execute) the script.

Some comments:

- This script file is very simple, just showing the idea of a script file rather than being a good example.
- Realizing how saving a script file works, it is not necessary to start all over to create the file, the total simulation can be saved, and afterwards the script file can be edited to keep only the wanted parts of the simulation. However, it is important to test it if created that way.
- More information about script files is available in the chapter “Simulating a model” in the manual for more information.

- Working with scripting using functions is even smarter, for more information please see the manual.

1.5 Building a mechanical model

We will now develop a more complex model, a 3D mechanical model of a pendulum called a Furuta pendulum. It has an arm rotating in a horizontal plane with a single or double pendulum attached to it, see below.

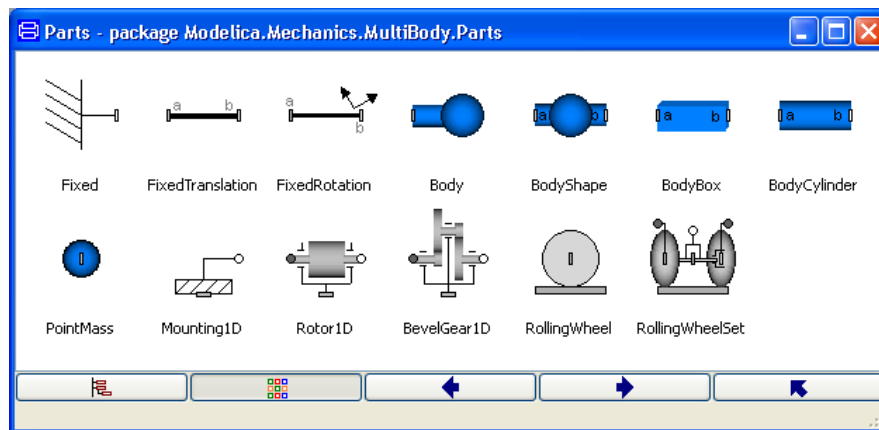

The Furuta pendulum.

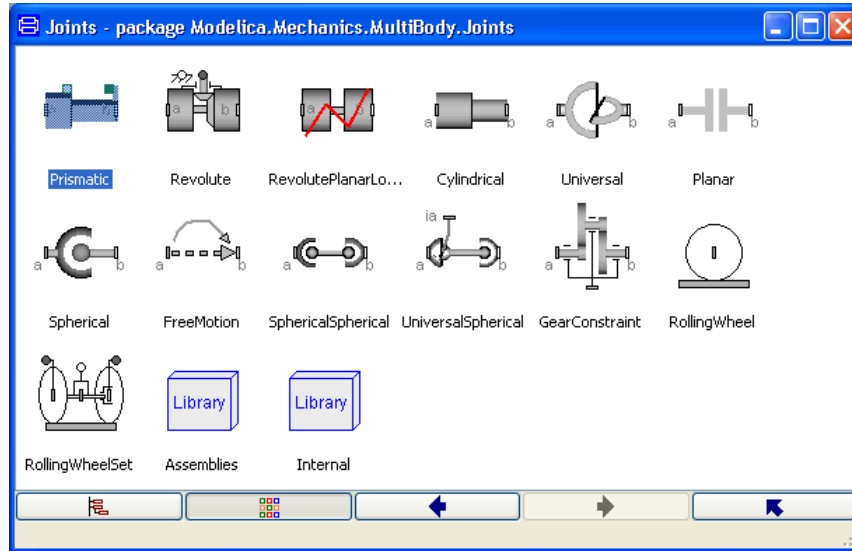

Start Dymola. Open Modelica Standard Library. In the package Mechanics open the sub-package MultiBody. This package includes 3D mechanical components such as joints and bodies, which can be used to build a model of the Furuta pendulum.

To build the Furuta pendulum, you will need to use the Parts and Joints sub-packages. If you open them in library windows by right-clicking on them in the package browser and using the command **Open Library Window** (and adapting the window) they will look the following:

The Parts sub-package library window.

The Joints sub-package library window.

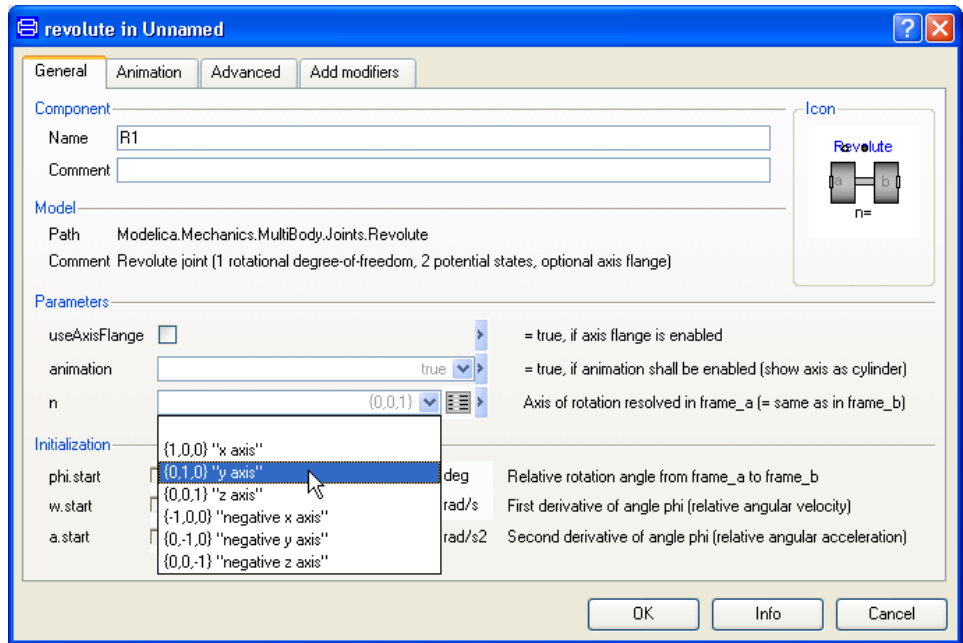

Select **File > New... > Model** and give the name **Furuta**.

The first step in building a MBS (MultiBody System) model is to define an inertial system. Drag the component World from the package browser (Multibody package) into the Furuta edit window. The default parameters need not be changed. (The gravity of acceleration is set to 9.81 and pointing in the negative direction of the y axis).

We then need a revolute joint. Drag the model Joints.Revolute onto the Furuta window. You can either drag from the package browser or the library window. Select **Edit > Rotate 90**. This just changes the appearance of the icon. Double-click on the icon.

Change the name to R1. The axis of rotation is set as the parameter n. We would like to have a vertical axis of rotation; use the list of choices and select "y axis". Click **OK**. Connect the connector of world to the bottom connector of the revolute joint.

A bar is then connected to the revolute joint. There is one bar which has the visual appearance of a box during animation, called BodyBox in the Parts library. Drag such a component to the edit window. Double-click on the icon. Name it B1. We would like the bar to be 0.5 long and initially horizontal and pointing in the positive x direction. This is specified by setting the vector r between the two ends of the body to $\{0.5, 0, 0\}$. Click on the **Edit** icon just to the right of the value field of r and a vector editor pops up. Enter 0.5 in the first field, 0 in the following two fields (you must specify the values since no default values are shown, otherwise you later will get an error message). Click **OK**. The width and height will be 0.1 by default.

To get nicer animation, you can set different colors for the bars. For example, use the list of choices of color to make the bar red.

From the bar B1, we connect another revolute joint, R2, having a horizontal axis of rotation, $n=\{1, 0, 0\}$ and a BodyBox, B2, (rotated -90), with $r=\{0, -0.5, 0\}$ and a different color than the first bar.

When simulating, the start values of R2 are interesting. Looking at the parameter dialog for R2 the initial value of the angle (phi.start), the initial velocity (w.start) and the relative angular acceleration (a.start) can be specified in the dialog. The idea is of course to specify values when simulating, but we have to specify what type of start values we want to use. This is done by clicking on the box after each start value. The choices are:

Choices for start values.

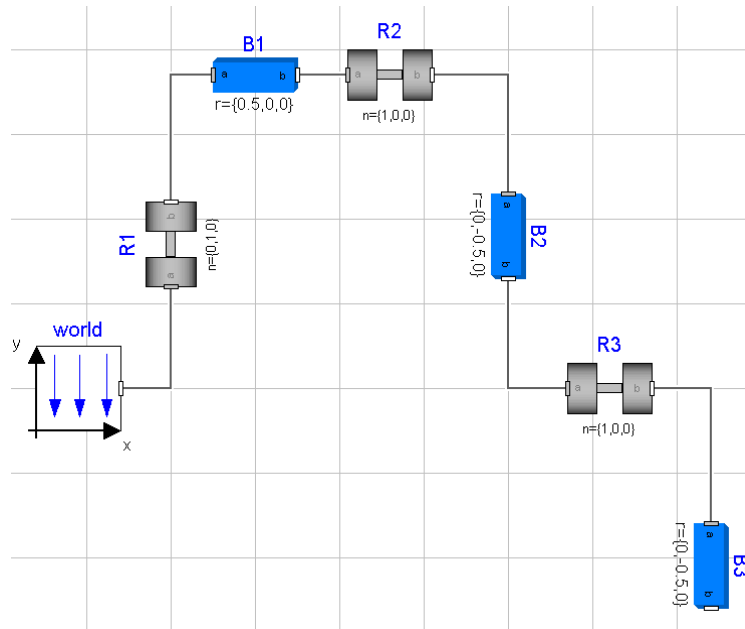

Actually we don't need to change anything, Dymola will itself take care of this, but we will have warnings when translating. In order to avoid these warnings, phi.start and w.start should be set to fixed=true using the menu above for all joints.

To get a double pendulum, create another similar joint and another BodyBox and connect them. This is accomplished easily by selecting the two components already present and choosing **Edit > Duplicate**. (The selection of the start value type for phi.start can be removed from R3 if wanted.)

You should now have arrived at a model that is similar to the following.

The diagram of the Furuta pendulum.

Now it is time to simulate. To enter the Simulation mode, click on the tab at the bottom right. The simulation menu is now activated and new tool bar buttons appear.

When building 3D mechanical models, it is possible to get visual feedback to check that the mechanical system is put together as intended. Click on the toolbar button **Visualize**. The animation window shows the initial configuration of the system.

Initial configuration of system.

Translate the model. In the variable browser, open R2 by clicking on the + in front of it and enter a value for ϕ_{start} , say 1 rad, and simulate for 5 seconds (use the command **Simulation > Setup...** to change the stop time). View the pendulum in the animation window; you may want to adjust the perspective when working with the robot (please see section “Simulation” on page 15 for tools used). It will be nicer to present it by e.g. moving it to the following position:

Initial configuration of system rotated around y axis.

(The representation of the revolute joints as cylinders can be changed using the parameter animation; if that is set to false the joint cylinders are not shown.)

Change parameters and study the different behavior.

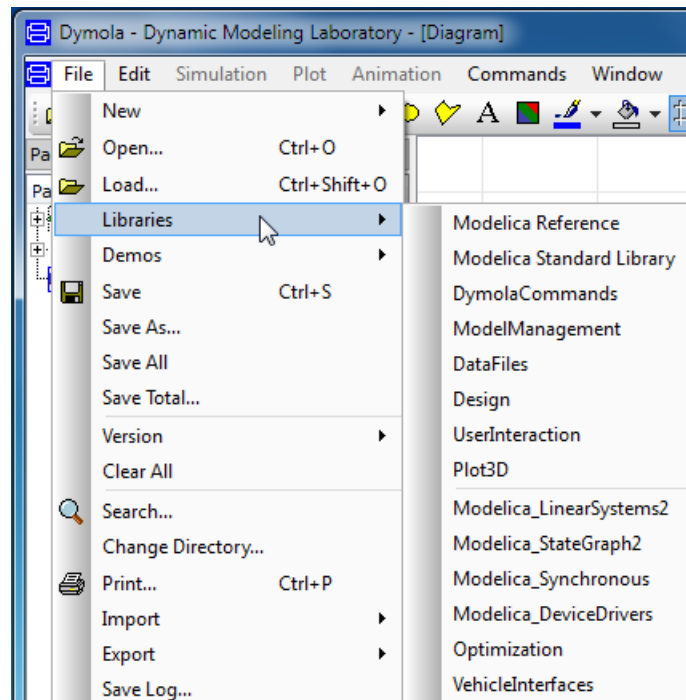

Try to control the pendulum in such a way as to get a stable upright position. (A trick is to use a “mechanical PD controller”, i.e. a spring and damper attached to the tip of the second bar and to a high position.)

1.6 Other libraries

1.6.1 Libraries available in the File menu by default

Using the command **File > Libraries** in a Dymola program with no extra libraries installed will at present display the following:

Libraries available when no optional library is installed.

Modelica Reference is the documentation of classes, operators etc from the Modelica Language Specification. There are no components that can be dragged from this library to the edit window, it is purely documentation. This library is free.

Modelica Standard Library has been dealt with earlier in this chapter. This library is free.

DymolaCommands contains selected commands (built-in functions). They are grouped in the same way as they are documented in chapter 5 in this manual (section “Scripting”, subsection “Built-in functions in Dymola”). Note that this library is automatically opened when opening Dymola.

Model Management deals with version management, model dependencies, encryption, model and library checking (including regression testing of libraries), model comparison and model structure. It cannot be used free, it demands a license. For more information, please see the manual “Dymola User Manual Volume 2”, chapter “Model Management”.

DataFiles contains functions for reading and writing data. For more information, please see chapter “Developing a model”, section “Advanced model editing”, sub-section “Using data from files”.

Design deals with four main areas:

- **Model calibration** makes it possible to calibrate and assess models. The Model Calibration option is required for problems with more than one tuner. For more information, please see the manual “Dymola User Manual Volume 2”, chapter “Model calibration”.
- **Model experimentation** gives the user possibility to vary parameters of the system to get an intuitive knowledge of the behavior of the model. Monte Carlo analysis is included. This part of the library is free. For more information, please see the manual “Dymola User Manual Volume 2”, chapter “Model Experimentation”.
- **Design optimization** is used to determine improved values of model parameters by multi-criteria optimization based on simulation runs. The Optimization option is required if used on more complex models. For more information, please see the manual “Dymola User Manual Volume 2”, chapter “Design optimization”. Note that a newer library is available also; please see “Optimization” below.
- **Model validation** supports validation and regression testing of a specified model. The idea is to compare the simulation result against reference data to check if for example changes in model libraries change the result. The reference data is assumed to be stored as trajectory files, which is the data format used by Dymola to store simulation results. When developing a model it is very natural and recommended to provide it with carefully checked reference simulation results. Please also compare the library “Model Management” where model validation and regression testing is supported on a larger scale.

UserInteraction enables changing parameters and inputs by numbers, sliders etc., as well as animation of simulation results. Please see the documentation in the package for more information.

Plot 3D is used to visualize models in 3D. This library is free.

Modelica_LinearSystems2 is a free library from Modelica Association providing different representations of linear, time invariant differential and difference equation systems, as well as typical operations on these system descriptions. See the documentation inside the package for details.

Modelica_StateGraph2 is a free library from Modelica Association providing components to model discrete event, reactive and hybrid systems in a convenient way with deterministic hierarchical state diagrams. It can be used in combination with any Modelica model. It has larger power than the package StateGraph in the Modelica Standard Library. See the documentation inside the library for details.

Modelica_Synchronous library is a free library from Modelica Association to precisely define and synchronize sampled data systems with different sampling rates. The library has elements to define periodic clocks and event clocks that trigger elements to sample, sub-sample, super-sample, or shift-sample partitions synchronously. Optionally, quantization effects, computational delay or noise can be simulated. Continuous-time equations can be automatically discretized and utilized in a sampled data system. The sample rate of a partition needs to be defined at one location only. All Modelica libraries designed so far for sampled systems, such as Modelica.Blocks.Discrete or Modelica_LinearSystems2.Controller are becoming obsolete and instead Modelica_Synchronous should be utilized.

Modelica_DeviceDrivers is a free library that allows accessing some external devices in Modelica models. Such external devices are input devices, communication devices, shared memory, analog-digital converters and else. This is achieved by using the Modelica external C interface to call the appropriate C driver functions provided by the underlying operating system. Currently Microsoft Windows and Linux are supported.

VehicleInterfaces is a free library providing standard interface definitions for automotive subsystems and vehicle models to promote compatibility between the various automotive libraries. See the documentation inside the library for details.

Optimization is a newer version of the Design optimization package in the Design library (see above). It contains much more functionality and should be used for new applications rather than the old one. For more information, see the manual for the library, which is available using the command **Help > Documentation**.

1.6.2 Libraries that can be added

There are a number of libraries available, both free and commercial ones. For an overview of them, please see <http://www.modelica.org/libraries>.

1.7 Help and information

1.7.1 Reaching compressed information

The What's This? command/button etc

The **What's This?** command is used to display information about many things. The command is activated in three different ways depending on where it should be used.

In the Main Dymola window

If more information should be obtained for e.g. a button or a symbol in the Dymola main window, the easiest way is to click on the **What's This?** button and then click on the symbol that is of interest. (The **Help** menu can also be used to activate this function.)

Please note that this button does not work in the Edit window.

In any dialog

In any dialog the **What's This?** is reachable using the ? in the upper corner of the window. Click on the ? and then on the field of interest. Please note that sometimes the information concerns (only) exactly what has been clicked on, sometimes the information concerns a group of signals etc.

In any menu

When displaying any menu, help for a certain entry is available by resting the cursor on it and then pressing **Shift+F1**.

Tooltips

By resting the cursor on any component or button a tooltip text is shown. For buttons it will be the name of the button, for components it will be the name of the component + the path to it.

The Search command/button

The search functionality can be reached either using the command **File > Search** or clicking the **Search** button. See chapter "Developing a model", section "Editor command reference - Modeling mode", sub-section "Main window: File menu", command "File > Search" for more information.

1.7.2 Reaching more extensive information

The Info command/button

If any component is selected in the Edit window or in the package or component browser, right-clicking will take up a context menu where the command **Info** is available. Inside a dialog a button **Info** is available instead.

The Help menu

The **Help** menu can be used to display manuals and to go to the Dymola website. The help menu also contains the license handling. The help menu is described in chapter “Developing a model”, section “Editor command reference - Modeling mode”, sub-section “Main window: Help menu”.

The Search command/button

The search functionality can be reached either using the command **File > Search** or clicking the **Search** button. For reference, please see the corresponding section above.

The documentation layer of Edit window

This layer can be used to display more extensive information about packages and components. Please see chapter “Developing a model”, section “Basic Model editing”, sub-section “Documentation” for more information. This type of documentation can also be exported to HTML files etc.

Books etc

Manuals are available for Dymola and a number of libraries used, as well as for the Modelica language.

1.8 Shortcuts

Shortcuts are available for a number of commands. The following is an overview of available shortcuts. Please note that very common shortcuts, e.g. Ctrl+C for Copy and Ctrl+V for Paste can be found in more locations than the one specified below.

File menu

Command	Shortcut
New Model	Ctrl+Shift+M
New Package	Ctrl+Shift+P
Duplicate Class	Ctrl+Shift+D
Open	Ctrl+O
Load	Ctrl+Shift+O
Save	Ctrl+S
Save All	Ctrl+Shift+S
Print	Ctrl+P

Edit menu

Command	Shortcut
Undo	Ctrl+Z
Redo	Ctrl+Y
Cut	Ctrl+X
Copy	Ctrl+C
Paste	Ctrl+V
Delete	Del
Duplicate	Ctrl+D
Select All	Ctrl+A
Find	Ctrl+F
Replace	Ctrl+H
Go To	Ctrl+G (text editor)
Align to grid	Ctrl+G (diagram/icon layer)
Manhattanize	Ctrl+M
Rotate 90	Ctrl+R

Rotate -90	Ctrl+Shift+R
Flip Horizontal	H
Flip Vertical	V
Check	F8

Simulation menu

Command	Shortcut
Translate	F9
Translate FMU	Ctrl+F9
Simulate	F10
Continue	F11
Stop	F12

Animation menu

Command	Shortcut
Run	F3
Pause	F4
Rewind	F7
Reverse	Shift+F6
Backstep	F6
Step Forward	F5
Forward	Shift+F5

Dymola main window

Command	Shortcut
Modeling	Ctrl+F1
Simulation	Ctrl+F2

Package browser

Command	Shortcut
Move Up	Ctrl+Up
Move Down	Ctrl+Down

Copy Path	Ctrl+C
-----------	--------

Diagram/icon layer

Command	Shortcut
Fit to Window	Ctrl+T

Modelica Text editor

Command	Shortcut
Hide All Annotations	Ctrl+1
Show Components and Connections	Ctrl+2
Show Entire Text	Ctrl+3
Highlight Syntax	Ctrl+L
Reformat Selection	Ctrl+Shift+L
Comment/Uncomment Selection	Ctrl+K
Insert Function Call	Ctrl+W
New Variable	Ctrl+N
Edit Function Call	Ctrl+U

Documentation layer: Info/revision editor + Command window

Command	Shortcut
Bold	Ctrl+B
Italic	Ctrl+I
Underline	Ctrl+U
Subscript	Ctrl+=
Superscript	Ctrl++

Default shortcuts for text editor in Qt

Action	Shortcut
Move one line up	Up
Move one line down	Down
Move one character to the left	Left
Move one character to the right	Right

Move one (viewpoint) page up	PageUp
Move one (viewpoint) page down	PageDown
Move to the beginning of the text	Home
Move to the end of the text	End
Scroll the page horizontally	Alt+Wheel
Zoom the text	Ctrl+Wheel
Select all text	Ctrl+A
