TABLE OF CONTENTS

PART I: EP7312 USER'S MANUAL

1. CONVENTIONS	10
1.1 Acronyms and Abbreviations	10
1.2 Units of Measurement	11
1.3 General Conventions	12
1.4 Pin Description Conventions	12
2. EP7312 FUNCTIONAL DESCRIPTION	13
2.1 CPU Core	14
2.2 State Control	15
2.2.1 Standby State	15
2.2.1.1 UART in Standby State	17
2.2.2 Idle State	17
2.2.3 Keyboard Interrupt	18
2.3 Power-Up Sequence	18
2.4 Resets	19
2.5 Clocks	20
2.5.1 On-Chip PLL	20
2.5.1.1 Characteristics of the PLL Interface	20
2.5.2 External Clock Input (13 MHz)	21
2.5.3 Dynamic Clock Switching When in the PLL Clocking Mode	22
2.6 Interrupt Controller	22
2.6.1 Interrupt Latencies in Different States	24
2.6.1.1 Operating State	24
2.6.1.2 Idle State	24
2.6.1.3 Standby State	24
2.7 EP7312 Boot ROM	26
2.8 Memory and I/O Expansion Interface	27
2.9 SDRAM Controller	28
2.10 SDRAM Initialization	31
2.11 CL-PS6700 PC Card Controller Interface	32
2.12 Serial Interfaces	35
2.13 CODEC Sound Interface	36
2.14 Endianness	37
2.15 Internal UARTs (Two) and SIR Encoder	39
2.15.1 Digital Audio Interface	40
2.15.1.1 DAI Operation	41
2.15.1.2 DAI Frame Format	42
2.15.1.3 DAI Signals	43

Contacting Cirrus Logic Support

For a complete listing of Direct Sales, Distributor, and Sales Representative contacts, visit the Cirrus Logic web site at:

1. CONVENTIONS

This section presents acronyms, abbreviations, units of measurement, and conventions used in this data sheet.

1.1 Acronyms and Abbreviations

Table 1 lists abbreviations and acronyms used in this data sheet.

Acronym/ Abbreviation	Definition
AC	alternating current
A/D	analog-to-digital
ADC	analog-to-digital converter
CAS	Column Address Strobe
CMOS	complementary metal oxide semiconductor
CODEC	coder / decoder
CPU	central processing unit
D/A	digital-to-analog
DC	direct current
DMA	direct-memory access
EPB	embedded peripheral bus
FCS	frame check sequence
FIFO	first in / first out
fs	Sample Frequency
GPIO	general purpose I/O
ICT	in circuit test
IR	infrared
IrDA	Infrared Data Association
JTAG	Joint Test Action Group
LCD	liquid crystal display
LED	light-emitting diode

Table 1. Acronyms and Abbreviations

Acronym/ Abbreviation	Definition
LQFP	low profile quad flat pack
LSB	least significant bit
MIPS	millions of instructions per second
MMU	memory management unit
MSB	most significant bit
PBGA	plastic ball grid array
PCB	printed circuit board
PDA	personal digital assistant
PIA	peripheral interface adapter
PLL	phase locked loop
PSU	power supply unit
p/u	pull-up resistor
RAM	random access memory
RAS	Row Address Strobe
RISC	reduced instruction set computer
ROM	read-only memory
RTC	Real Time Clock
SDRAM	Synchronous Dynamic RAM
SIR	slow (9600–115.2 kbits/s) infrared
SRAM	static random access memory
SSI	synchronous serial interface
TAP	test access port
TLB	translation lookaside buffer
UART	universal asynchronous receiver

Table 1. Acronyms and Abbreviations (cont.)

1.2 Units of Measurement

Symbol	Unit of Measure
°C	degree Celsius
fs	sample frequency
Hz	hertz (cycle per second)
kbits/s	kilobits per second
kbyte	kilobyte (1,024 bytes)
kHz	kilohertz
kΩ	kilohm
Mbits/s	megabits (1,048,576 bits) per second
Mbyte	megabyte (1,048,576 bytes)
MHz	megahertz (1,000 kilohertz)
μA	microampere
μF	microfarad
μW	microwatt
μs	microsecond (1,000 nanoseconds)
mA	milliampere
mW	milliwatt
ms	millisecond (1,000 microseconds)
ns	nanosecond
V	volt
W	watt

Table 2. Unit of Measurement

1.3 General Conventions

Hexadecimal numbers are presented with all letters in uppercase and a lowercase “h” appended or with a 0x at the beginning. For example, 0x14 and 03CAh are hexadecimal numbers. Binary numbers are enclosed in single quotation marks when in text (for example, ‘11’ designates a binary number). Numbers not indicated by an “h,” 0x, or single quotation marks are decimal.

Registers are referred to by acronym, with bits listed in brackets separated by a hyphen (-) (for example, CODR[0-7]).

The use of “tbd” indicates values that are “to be determined,” “n/a” designates “not available,” and “n/c” indicates a pin that is a “no connect.”

1.4 Pin Description Conventions

Abbreviations used for signal directions are listed in Table 3.

Abbreviation	Direction
I	Input
O	Output
I/O	Input or Output

Table 3. Pin Description Conventions

2. EP7312 FUNCTIONAL DESCRIPTION

The EP7312 device is a single-chip embedded controller designed to be used in low-cost and ultra-low-power applications. Operating at 74 MHz, the EP7312 delivers approximately 66 Dhrystone 2.1 MIPS of sustained performance (74 MIPS peak). This is approximately the same as a 100 MHz Pentium-based PC.

The EP7312 contains the following functional blocks:

- ARM720T processor which consists of the following functional sub-blocks:
 - ARM7TDMI CPU core (which supports the logic for the Thumb instruction set, core debug, enhanced multiplier, JTAG, and the Embedded ICE) running at a dynamically programmable clock speed of 18 MHz, 36 MHz, 49 MHz, or 74 MHz.
 - Memory Management Unit (MMU) compatible with the ARM710 core (providing address translation and a 64-entry translation lookaside buffer) with added support for Windows CE.
 - 8 kbytes of unified instruction and data cache with a four-way set associative cache controller.
 - Write buffer
- 48 kbytes (0x9600) of on-chip SRAM that can be shared between the LCD controller and general application use.
- Memory interfaces for up to 6 independent 256 Mbyte expansion segments with programming wait states.
- 27 bits of general purpose I/O - multiplexed to provide additional functionality where necessary.
- Digital Audio Interface (DAI) for connection to CD-quality DACs and CODECs.
- Interrupt controller
- Advanced system state control and power management.
- Two full-duplex 16550A compatible UARTs with 16-byte transmit and receive FIFOs.
- IrDA SIR protocol controller capable of speeds up to 115.2 kbits/s.
- Programmable 1-, 2-, or 4-bit-per-pixel LCD controller with 16-level grayscale.
- Programmable frame buffer start address, allowing a system to be built using only internal SRAM for memory.
- On-chip boot ROM programmed with serial load boot sequence.
- Two 16-bit general purpose timer counters.
- A 32-bit Real Time Clock (RTC) and comparator.
- Dedicated LED flasher pin driven from the RTC with programmable duty ratio (multiplexed with a GPIO pin).
- Two synchronous serial interfaces for Micro-wire or SPI peripherals such as ADCs, one supporting both the master and slave mode and the other supporting only the master mode.
- Full JTAG boundary scan and Embedded ICE support.
- Two programmable pulse-width modulation interfaces.
- An interface to one or two Cirrus Logic CL-PS6700 PC Card controller devices to support two PC Card slots.
- Direct SDRAM interface operates at up to 36.864 MHz with 4 internal banks totaling 256 Mbits in size. The SDRAM interface can be configured for 16-bit or 32-bit wide accesses.
- Oscillator and phase-locked loop (PLL) to generate the core clock speeds of 18.432 MHz, 36.864 MHz, 49.152 MHz, and 73.728 MHz from an external 3.6864 MHz crystal.
- An alternative external clock input at 13 MHz.
- A low-power 32.768 kHz oscillator that generates the RTC.

A simplified block diagram of the EP7312 is shown in Figure 1. All external memory and peripheral devices are connected to the 32-bit data bus using the external 28-bit address bus and control signals.

2.1 CPU Core

The ARM720T consists of an ARM7TDMI 32-bit RISC processor, a unified cache, and a memory management unit (MMU). The cache is four-way set associative with 8-kbytes organized as 512 lines of 4 words. The cache is directly connected to the ARM7TDMI, and therefore caches the virtual address from the CPU. When the cache misses, the MMU translates the virtual address into a physical address. A 64-entry translation lookaside buffer (TLB) is utilized to speed the address translation process and reduce bus traffic necessary to read the page table. The MMU saves power by only translating the cache misses.

See the *ARM720T Data Sheet* for a complete description of the various logic blocks that make up the processor, as well as all internal register information. The URL (Internet address) for ARM technical manuals is <http://www.arm.com/Documentation/Manuals/>.

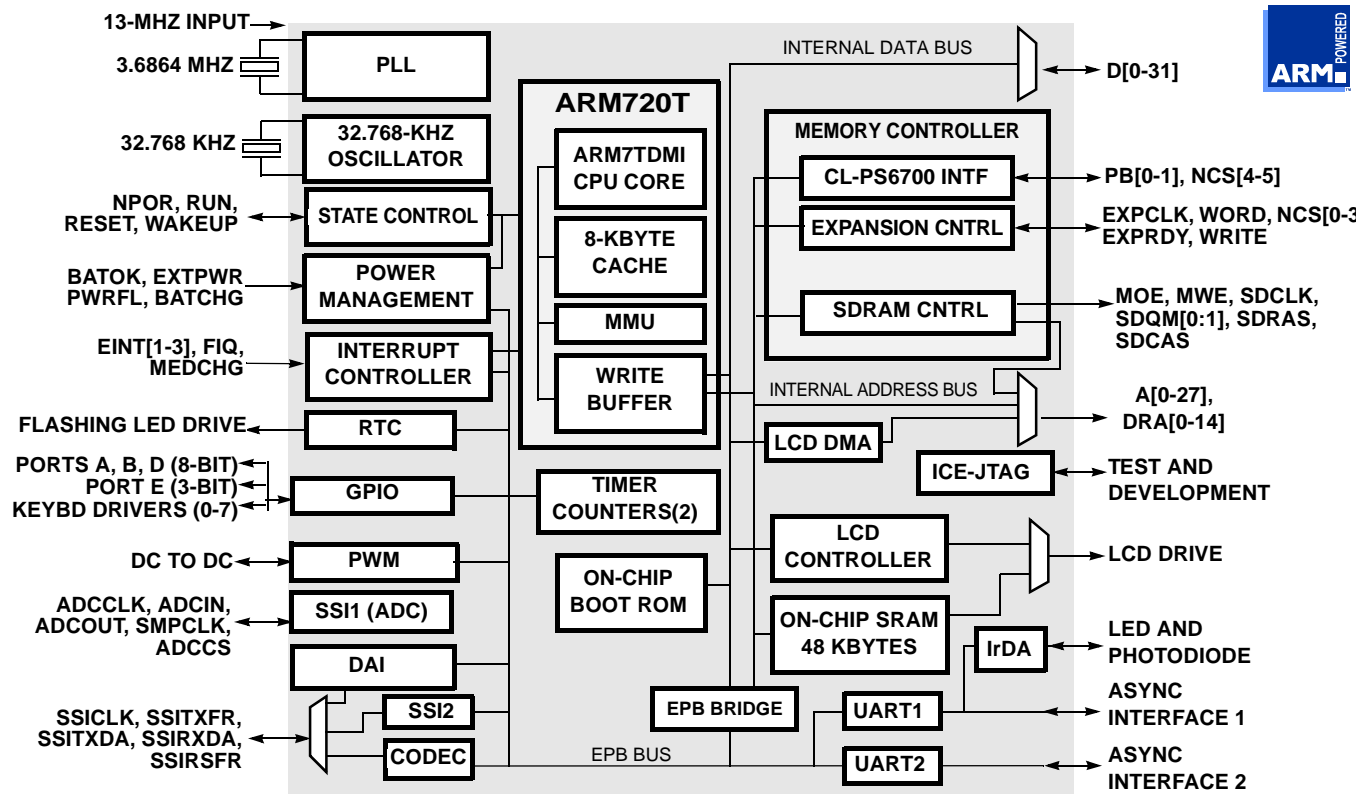

Figure 1. EP7312 Block Diagram

2.2 State Control

The EP7312 supports the following Power Management States: Operating, Idle, and Standby (see Figure 2). The normal program execution state is the Operating State; this is a full performance state where all of the clocks and peripheral logic are enabled. The Idle State is the same as the Operating State except that the CPU clock is halted. An interrupt from an external interrupt source or from the real-time clock will return it back to the Operating State. The WAKEUP signal can only be used to exit the Standby State, not the Idle State. The Standby State has the lowest power consumption of the three states. By selecting this mode the main oscillator shuts down, leaving only the Real Time Clock and its associated logic powered. It is important when the EP7312 is in Standby that all power and ground pins remain connected to power and ground in order to have a proper system wake-up. The only state that Standby can transition to is the Operating State.

In the description below, the RUN/CLKEN pin can be used either for the RUN functionality, or the CLK-EN functionality to allow an external oscillator to be disabled in the 13 MHz mode. Either RUN or CLKEN functionality can be selected according to the state of the CLKENSL bit in the SYSCON2 register. Table 4 on page 16 on the following page shows peripheral status in various power management states.

2.2.1 Standby State

The Standby State equates to the system being switched “off” (i.e., no display, and the main oscillator is shut down). When the 18.432–73.72 MHz mode is selected, the PLL will be shut down. In the 13 MHz mode, if the CLKENSL bit is set low, then the CLKEN signal will be forced low and can, if required, be used to disable an external oscillator.

In the Standby State, all the system memory and state is maintained and the system time is kept up-to-date. The PLL-on-chip oscillator or external oscillator is disabled and the system is static, except for the low power watch crystal (32 kHz) oscillator and divider chain to the RTC and LED flasher. The RUN signal is driven low, therefore this signal can be used externally in the system to power down other system modules.

Whenever the EP7312 is in the Standby State, the external address and data buses are forced low internally by the RUN signal. This is done to prevent peripherals that are powered down from draining current. Also, the internal peripheral’s signals get set to their Reset State.

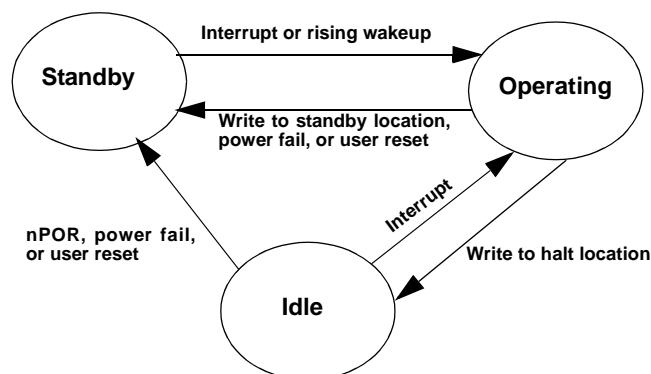

Figure 2. State Diagram

When first powered, or reset by the nPOR (Power On Reset, active low) signal, the EP7312 is forced into the Standby State. This is known as a cold reset, and when leaving the Standby State after a cold reset, external wake up is the only way to wake up the device. When leaving the Standby State after non-cold reset conditions (i.e., the software has forced the device into the Standby State), the transition to the Operating State can be caused by a rising edge on the WAKEUP input signal or by an enabled interrupt. Normally, when entering the Standby State from the Operating State, the software will leave some interrupt sources enabled.

Note: The CPU cannot be awakened by the TINT, WEINT, and BLINT interrupts when in the Standby State.

Address (W/B)	Operating	Idle	Standby	nPOR RESET	nURESET RESET
SDRAM Control	On	On	SELFREF	Off	N/A
UARTs	On	On	Off	Reset	Reset
LCD FIFO	On	On	Reset	Reset	Reset
LCD	On	On	Off	Reset	Reset
ADC Interface	On	On	Off	Reset	Reset
SSI2 Interface	On	On	Off	Reset	Reset
DAI Interface	On	On	Off	Reset	Reset
CODEC	On	On	Off	Reset	Reset
Timers	On	On	Off	Reset	Reset
RTC	On	On	On	On	On
LED Flasher	On	On	On	Reset	Reset
DC-to-DC	On	On	Off	Reset	Reset
CPU	On	Off	Off	Reset	Reset
Interrupt Control	On	On	On	Reset	Reset
PLL/CLKEN Signal	On	On	Off	Off	Off

Table 4. Peripheral Status in Different Power States

Typically, software writes to the Standby internal memory location to cause the transition from the Operating State to the Standby State. Before entering the Standby State, if external I/O devices (such as the CL-PS6700s connected to nCS[4] or nCS[5]) are in use, the software must check to ensure that they are idle before issuing the write to the Standby State location.

Before entering the Standby State, the software must properly disable the DAI. Failing to do so will result in higher than expected power consumption in the Standby State, as well as unpredictable operation of the DAI. The DAI can be re-enabled after transitioning back to the Operating State.

The system can also be forced into the Standby State by hardware if the nPWRFL or nURESET inputs are forced low. The only exit from the Standby State is to the Operating State.

The system will only transition to the Operating State from the Standby State under the following conditions: when the nPWRFL input pin is high when the nEXTPWR input pin is low or when the BATOK input pin is high. This prevents the system from starting when the power supply is inadequate (i.e., the main batteries are low), corresponding to a low level on nPWRFL or BATOK.

From the Standby State, if the WAKEUP signal is applied with no clock except the 32 kHz clock running, the EP7312 will be initialized into a state where it is ready to start and is waiting for the CPU to start receiving its clock. The CPU will still be held in reset at this point. After the first clock is applied, there will be a delay of about eight clock cycles before the CPU is enabled. This delay is to allow the clock to the CPU time to settle.

2.2.1.1 UART in Standby State

During the Standby State, the UARTs are disabled and cannot detect any activity (i.e., start bit) on the receiver. If this functionality is required then this can be accomplished in software by the following method:

- 1) Permanently connect the RX pin to one of the active low external interrupt pins.
- 2) Ensure that on entry to the Standby State, the chosen interrupt source is not masked, and the UART is enabled.
- 3) Send a preamble that consists of one start bit, 8 bits of zero, and one stop bit. This will cause the EP7312 to wake and execute the enabled interrupt vector.

The UART will automatically be re-enabled when the processor re-enters the Operating State, and the preamble will be received. Since the UART was not awake at the start of the preamble, the timing of the sample point will be off-center during the preamble byte. However, the next byte transmitted will be correctly aligned. Thus, the actual first real byte to be received by the UART will get captured correctly.

2.2.2 Idle State

If in the Operating State, the Idle State can be entered by writing to a special internal memory location (HALT) in the EP7312. If an interrupt occurs, the EP7312 will return immediately back to the Operating State and execute the next instruction. The WAKEUP signal can not be used to exit the Idle State. It is only used to exit the Standby State.

In the Idle State, the device functions just like it does when in the Operating State. However, the CPU clock is halted while it waits for an event such as a key press to generate an interrupt. The PLL (in 18.432–73.728 MHz mode) or the external 13 MHz clock source always remains active in the Idle State.

2.2.3 Keyboard Interrupt

For the case of the keyboard interrupt, the following options are available and are selectable according to bits 1 and 3 of the SYSCON2 register (refer to the *SYSCON2 Register Description* for details).

- If the KBWEN bit (SYSCON2 bit 3) is set low, then a keypress will cause a transition from a power saving state only if the keyboard interrupt is non-masked (i.e., the interrupt mask register 2 (INTMR2 bit 0) is high).
- When KBWEN is high, a keypress will cause the device to wake up regardless of the state of the interrupt mask register. This is called the “Keyboard Direct Wakeup” mode. In this mode, the interrupt request may not get serviced. If the interrupt is masked (i.e., the interrupt mask register 2 (INTMR2 bit 0) is low), the processor simply starts re-executing code from where it left off before it entered the power saving state. If the interrupt is non-masked, then the processor will service the interrupt.
- When the KBD6 bit (SYSCON2 bit 1) is low, all 8 of Port A inputs are OR’ed together to produce the internal wakeup signal and keyboard interrupt request. This is the default reset state.
- When the KBD6 bit (SYSCON2 bit 1) is high, only the lowest 6 bits of Port A are OR’ed together to produce the internal wakeup signal and keyboard interrupt request. The two most significant bits of Port A are available as GPIO when this bit is set high.

In the case where KBWEN is low and the INTMR2 bit 0 is low, it will only be possible to wakeup the device by using the external WAKEUP pin or another enabled interrupt source. The keyboard interrupt capability allows an OS to use either a polled or interrupt-driven keyboard routine, or a combination of both.

Note: The keyboard interrupt is NOT debounced.

2.3 Power-Up Sequence

The EP7312 has a power-up sequence that should be followed for proper start up. If any of the recommended timing sequences below are violated, then it is possible that the part may not start-up properly. This could cause the device to get lost and not recover without a hard reset.

- 1) Upon power, the signal nPOR must be held active (LOW) for a minimum of 100 ms, after V_{DD} has become settled.
- 2) After nPOR goes HIGH, the EP7312 will enter the Standby State (and only this state). In this state, the PLL is not enabled, and thus the CPU is not enabled either. The only method that can be used to allow the EP7312 to exit the Standby State into the Operating State is by the WAKEUP signal going active (HIGH).

Note: Do not assert the nRESET signal before the processor goes into Operating State. This is due to the fact that nRESET is latched into the device by the rising edge of nPOR. When nRESET is LOW on the rising edge of nPOR, it can force the device into one of its Test Mode states.

- 1) After nPOR goes HIGH, the WAKEUP signal cannot be detected as going HIGH, until after at least two seconds. After two seconds, the WAKEUP signal can become active, and it must be HIGH for at least 125 ms.
- 2) After the WAKEUP signal is detected internally, it first goes through a deglitching circuit. This is why it must be active for at least 125 ms. Then the PLL gets enabled. WAKEUP is ignored immediately after waking up the system. It also ignores it while in the Idle or Operating State. It can constantly toggle with no effect on the device. It will only be read again if nPOR goes low and then high again, or if software has forced the device back into the Standby State.
- 3) A maximum of 250 ms will pass before the CPU becomes enabled and starts to fetch the first instruction.

2.4 Resets

There are three asynchronous resets to the EP7312: nPOR, nPWRFL, and nURESET. If any of these are active, a system reset is generated internally. This will reset all internal registers in the EP7312 except the RTC data and match registers. These registers are only cleared by nPOR allowing the system time to be preserved through a user reset or power fail condition.

Any reset will also reset the CPU and cause it to start execution at the reset vector when the EP7312 returns to the Operating State.

Internal to the EP7312, three different signals are used to reset storage elements. These are nPOR, nSYSRES and nSTBY. nPOR is an external signal. nSTBY is equivalent to the external RUN signal.

nPOR (Power On Reset, active low) is the highest priority reset signal. When active (low), it will reset all storage elements in the EP7312. nPOR active forces nSYSRES and nSTBY active. nPOR will only be active after the EP7312 is first powered up and not during any other resets. nPOR active will clear all flags in the status register except for the cold reset flag (CLDFLG) bit (SYSFLG, bit 15), which is set.

nSYSRES (System Reset, active low) is generated internally to the EP7312 if nPOR, nPWRFL, or nURESET are active. It is the second highest priority reset signal, used to asynchronously reset most internal registers in the EP7312. nSYSRES active forces nSTBY and RUN low. nSYSRES is used to reset the EP7312 and force it into the Standby State with no co-operation from software. The CPU is also reset.

The nSTBY and RUN signals are high when the EP7312 is in the Operating or Idle States and low when in the Standby State. The main system clock is valid when nSTBY is high. The nSTBY signal will disable any peripheral block that is clocked from the master clock source (i.e., everything except for the RTC). In general, a system reset will clear all registers and nSTBY will disable all peripherals that require a main clock. The following peripherals are always disabled by a low level on nSTBY: two UARTs and IrDA SIR encoder, timer counters, telephony CODEC, and the two SSI interfaces. In addition, when in the Standby State, the LCD controller and PWM drive are also disabled.

When operating from an external 13 MHz oscillator which has become disabled in the Standby State by using the CLKEN (SYSCON, bit 13) signal (i.e., with CLKENSL = 0), the oscillator must be stable within 0.125 sec from the rising edge of the CLKEN signal.

2.5 Clocks

There are two clocking modes for the EP7312. Either an external clock input can be used or the on-chip PLL. The clock source is selected by a strapping option on Port E, pin 2 (PE[2]). If PE[2] is high at the rising edge of nPOR (i.e., upon power-up), the external clock mode is selected. If PE[2] is low, then the on-chip PLL mode is selected. After power-up, PE[2] can be used as a GPIO.

The EP7312 device contains several separate sections of logic, each clocked according to its own clock frequency requirements. When the EP7312 is in external clock mode, the actual frequencies at the peripherals will be different than when in PLL mode. See each peripheral device section for more details. The section below describes the clocking for both the ARM720T and address/data bus.

2.5.1 On-Chip PLL

The ARM720T clock can be programmed to 18.432 MHz, 36.864 MHz, 49.152 MHz, or 73.728 MHz with the PLL running at twice the highest possible CPU clock frequency (147.456 MHz). The PLL uses an external 3.6864 MHz crystal. By chip default, the on-chip PLL is used and configured such that the ARM720T and address/data buses run at 18.432 MHz.

When the clock frequency is selected to be 36 MHz, both the ARM720T and the address/data buses are clocked at 36 MHz. When the clock frequency is selected higher than 36 MHz, only the ARM720T gets clocked at this higher speed. The address/data will be fixed at 36 MHz. The clock frequency used is selected by programming the CLKCTL[1:0] bits in the SYSCON3 register. The clock frequency selection does not effect the EPB (external peripheral bus). Therefore, all the peripheral clocks are fixed, regardless of the clock speed selected for the ARM720T.

Note: After modifying the CLKCTL[1:0] bits, the next instruction should always be a "NOP."

2.5.1.1 Characteristics of the PLL Interface

When connecting a crystal to the on-chip PLL interface pins (i.e. MOSCIN and MOSCOUT), the crystal and circuit should conform to the following requirements:

- The 3.6864 MHz frequency should be created by the crystal's fundamental tone (i.e., it should be a fundamental mode crystal).
- A start-up resistor is not necessary, since one is provided internally.
- Start-up loading capacitors may be placed on each side of the external crystal and ground. Their value should be in the range of 10 pF. However, their values should be selected based upon the crystal specifications. The total sum of the capacitance of the traces between the EP7312's clock pins, the capacitors, and the crystal leads should be subtracted from the crystal's specifications when determining the values for the loading capacitors.
- The crystal should have a maximum 100 ppm frequency drift over the chip's operating temperature range.

Alternatively, a digital clock source can be used to drive the MOSCIN pin of the EP7312. With this approach, the voltage levels of the clock source should match that of the V_{DD} supply for the EP7312's pads

(i.e. the supply voltage level used to drive all of the non- V_{DD} core pins on the EP7312). The output clock pin (i.e., MOSCOUT) should be left floating.

2.5.2 External Clock Input (13 MHz)

An external 13 MHz crystal oscillator can be used to drive all of the EP7312. When selected the ARM720T and the address/data buses both get clocked at 13 MHz. The fixed clock sources to the various peripherals will have different frequencies than in the PLL mode. In this configuration, the PLL will not be used at all.

Note: When operating at 13 MHz, the CLKCTL[1:0] bits should not be changed from their default value of "00."

Figure 3. CLKEN Timing Entering the Standby State

Figure 4. CLKEN Timing Exiting the Standby State

2.5.3 Dynamic Clock Switching When in the PLL Clocking Mode

The clock frequency used for the CPU and the buses is controlled by programming the CLKCTL[1:0] bits in the SYSCON3 register. When this occurs, the state controller switches from the current to the new clock frequency as soon as possible without causing a glitch on the clock signals. The glitch-free clock switching logic waits until the clock that is currently in use and the newly programmed clock source are both low, and then switches from the previous clock to the new clock without a glitch on the clocks.

2.6 Interrupt Controller

When unexpected events arise during the execution of a program (i.e., interrupt or memory fault) an exception is usually generated. When these exceptions occur at the same time, a fixed priority system determines the order in which they are handled. Table 5 shows the priority order of all the exceptions.

The EP7312 interrupt controller has two interrupt types: interrupt request (IRQ) and fast interrupt request (FIQ). The interrupt controller has the ability to control interrupts from 22 different FIQ and IRQ sources. Of these, seventeen are mapped to the IRQ input and five sources are mapped to the FIQ input. FIQs have a higher priority than IRQs. If two interrupts are received from within the same group (IRQ or FIQ), the order in which they are serviced must be resolved in software. The priorities are listed in Table 5. All interrupts are level sensitive; that is, they must conform to the following sequence.

Priority	Exception
Highest	Reset
.	Data Abort
.	FIQ
.	IRQ
.	Prefetch Abort
Lowest	Undefined Instruction, Software Interrupt

Table 5. Exception Priority Handling

- 1) The interrupting device (either external or internal) asserts the appropriate interrupt.
- 2) If the appropriate bit is set in the interrupt mask register, then either a FIQ or an IRQ will be asserted by the interrupt controller. (A description for each bit in this register can be found in *Section 6.3.1 INTSR1 — Interrupt Status Register 1*.)
- 3) If interrupts are enabled the processor will jump to the appropriate address.
- 4) Interrupt dispatch software reads the interrupt status register to establish the source(s) of the interrupt and calls the appropriate interrupt service routine(s).
- 5) Software in the interrupt service routine will clear the interrupt source by some action specific to the device requesting the interrupt (i.e., reading the UART RX register).

The interrupt service routine may then re-enable interrupts, and any other pending interrupts will be serviced in a similar way. Alternately, it may return to the interrupt dispatch code, which can check for any more pending interrupts and dispatch them accordingly. The “End of Interrupt” type interrupts are latched. All other interrupt sources (i.e., external interrupt source) must be held active until its respective service routine starts executing. See “*End Of Interrupt Locations*” for more details.

Table 6, Table 7, and Table 8 show the names and allocation of interrupts in the EP7312.

Interrupt	Bit in INTMR1 and INTSR1	Name	Comment
FIQ	0	EXTFIQ	External fast interrupt input (nEXTFIQ pin)
FIQ	1	BLINT	Battery low interrupt
FIQ	2	WEINT	Tick Watchdog expired interrupt
FIQ	3	MCINT	Media changed interrupt
IRQ	4	CSINT	CODEC sound interrupt
IRQ	5	EINT1	External interrupt input 1 (nEINT[1] pin)
IRQ	6	EINT2	External interrupt input 2 (nEINT[2] pin)
IRQ	7	EINT3	External interrupt input 3 (EINT[3] pin)
IRQ	8	TC1OI	TC1 underflow interrupt
IRQ	9	TC2OI	TC2 underflow interrupt
IRQ	10	RTCMI	RTC compare match interrupt
IRQ	11	TINT	64 Hz tick interrupt
IRQ	12	UTXINT1	Internal UART1 transmit FIFO empty interrupt
IRQ	13	URXINT1	Internal UART1 receive FIFO full interrupt
IRQ	14	UMSINT	Internal UART1 modem status changed interrupt
IRQ	15	SSEOTI	Synchronous serial interface 1 end of transfer interrupt

Table 6. Interrupt Allocation for the First Interrupt Register

Interrupt	Bit in INTMR2 and INTSR2	Name	Comment
IRQ	0	KBDINT	Key press interrupt
IRQ	1	SS2RX	Master / slave SSI 16 bytes received
IRQ	2	SS2TX	Master / slave SSI 16 bytes transmitted
IRQ	12	UTXINT2	UART2 transmit FIFO empty interrupt
IRQ	13	URXINT2	UART2 receive FIFO full interrupt

Table 7. Interrupt Allocation in the Second Interrupt Register

Interrupt	Bit in INTMR3 and INTSR3	Name	Comment
FIQ	0	DAIINT	DAI interface interrupt

Table 8. Interrupt Allocation in the Third Interrupt Register

2.6.1 *Interrupt Latencies in Different States*

2.6.1.1 *Operating State*

The ARM720T processor checks for a low level on its FIQ and IRQ inputs at the end of each instruction. The interrupt latency is therefore directly related to the amount of time it takes to complete execution of the current instruction when the interrupt condition is detected. First, there is a one to two clock cycle synchronization penalty. For the case where the EP7312 is operating at 13 MHz with a 16-bit external memory system, and instruction sequence stored in one wait state FLASH memory, the worst-case interrupt latency is 251 clock cycles. This includes a delay for cache line fills for instruction prefetches, and a data abort occurring at the end of the LDM instruction, and the LDM being non-quad word aligned. In addition, the worst-case interrupt latency assumes that LCD DMA cycles to support a panel size of 320 x 240 at 4 bits-per-pixel, 60 Hz refresh rate, is in progress.

This would give a worst-case interrupt latency of about 19.3 μ s for the ARM720T processor operating at 13 MHz in this system. For those interrupt inputs which have de-glitching, this figure is increased by the maximum time required to pass through the deglitcher, which is approximately 125 μ s (2 cycle of the 16.384 kHz clock derived from the RTC oscillator). This would create an absolute worst-case latency of approximately 141 μ s. If the ARM720T is run at 36 MHz or greater and/or 32 bit wide external memory, the 19.3 μ s value will be reduced.

All the serial data transfer peripherals included in the EP7312 (except for the master-only SSI1) have local buffering to ensure a reasonable interrupt latency response requirement for the OS of 1 ms or less. This assumes that the design data rates do not exceed the data rates described in this specification. If the OS cannot meet this requirement, there will be a risk of data over/underflow occurring.

2.6.1.2 *Idle State*

When leaving the Idle State as a result of an interrupt, the CPU clock is restarted after approximately two clock cycles. However, there is still potentially up to 20 μ s latency as described in the first section above, unless the code is written to include at least two single cycle instructions immediately after the write to the IDLE register (in which case the latency drops to a few microseconds).

This is important, as the Idle State can only be left because of a pending interrupt, which has to be synchronized by the processor before it can be serviced.

2.6.1.3 *Standby State*

The Standby State equates to the system being switched “off” (i.e., no display, and the main oscillator is shut down). When the 18.432–73.72 MHz mode is selected, the PLL will be shut down. In the 13 MHz mode, if the CLKENSL bit is set low, then the CLKEN signal will be forced low and can, if required, be used to disable an external oscillator.

In the Standby State, all the system memory and state is maintained and the system time is kept up-to-date. The PLL/on-chip oscillator or external oscillator is disabled and the system is static, except for the low-power watch crystal (32 kHz) oscillator and divider chain to the RTC and LED flasher. The RUN signal is driven low, therefore this signal can be used externally in the system to power down other system modules.

Whenever the EP7312 is in the Standby State, the external address and data buses are driven low. The RUN signal is used internally to force these buses to be driven low. This is done to prevent peripherals that are power-down from draining current.

Also, the internal peripheral's signals get set to their Reset State.

Table 9 summarizes the five external interrupt sources and the effect they have on the processor interrupts.

Interrupt Pin	Input State	Operating State Latency	Idle State Latency	Standby State Latency
nEXTFIQ	Not deglitched; must be active for 20 μ s to be detected	Worst-case latency of 20 μ s	Worst-case 20 μ s: if only single cycle instructions, less than 1 μ s	Including PLL / osc. settling time, approx. 0.25 sec, or approx. 500 μ s when in Idle State if in 13 MHz mode with CLKENSL set
nEINT1–2	Not deglitched	Worst-case latency of 20 μ s	Worst-case 20 μ s: if only single cycle instructions, less than 1 μ s	Including PLL / osc. settling time, approx. 0.25 sec, or approx. 500 μ s when in Idle State if in 13 MHz mode with CLKENSL set.
EINT3	Not deglitched	Worst-case latency of 19.3 μ s	Worst-case 20 μ s: if only single cycle instructions, less than 1 μ s	Including PLL / osc. settling time, approx. 0.25 sec, or approx. 500 μ s when in Idle State if in 13 MHz mode with CLKENSL set.
nMEDCHG	Deglitched by 16.384 kHz clock; must be active for at least 122 μ s to be detected	Worst-case latency of 141 μ s	Worst-case latency 141 μ s; if any single cycle instructions = 125 μ s	As above (note difference if in 13 MHz mode with CLKENSL set)

Table 9. External Interrupt Sources

2.7 EP7312 Boot ROM

The 128 bytes of on-chip Boot ROM contain an instruction sequence that initializes the device and then configures UART1 to receive 2048 bytes of serial data that will then be placed in the on-chip SRAM. Once the download is complete, execution jumps to the start of the on-chip SRAM. This would allow, for example, code to be downloaded to program system FLASH during a product’s manufacturing process. See *Appendix A: Boot Code* for details of the ROM Boot Code with comments to describe the stages of execution.

Selection of the Boot ROM option is determined by the state of the nMEDCHG pin during a power on reset. If nMEDCHG is high while nPOR is active, then the EP7312 will boot from an external memory device connected to CS[0] (normal boot mode). If nMEDCHG is low, then the boot will be from the on-chip ROM. Note that in both cases, following the de-assertion of power on reset, the EP7312 will be in the Standby State and requires a low-to-high transition on the external WAKEUP pin in order to actually start the boot sequence.

The effect of booting from the on-chip Boot ROM is to reverse the decoding for all chip selects internally. Table 10 shows this decoding. The control signal for the boot option is latched by nPOR, which means that the remapping of addresses and bus widths will continue to apply until nPOR is asserted again. After booting from the Boot ROM, the contents of the Boot ROM can be read back from address 0x0000.0000 onwards, and in normal state of operation the Boot ROM contents can be read back from address range 0x7000.0000.

Address Range	Chip Select
0000.0000–0FFF.FFFF	CS[7] (Internal only)
1000.0000–1FFF.FFFF	CS[6] (Internal only)
2000.0000–2FFF.FFFF	nCS[5]
3000.0000–3FFF.FFFF	nCS[4]
4000.0000–4FFF.FFFF	nCS[3]
5000.0000–5FFF.FFFF	nCS[2]
6000.0000–6FFF.FFFF	nCS[1]
7000.0000–7FFF.FFFF	nCS[0]

Table 10. Chip Select Address Ranges After Boot from On-Chip Boot ROM

2.8 Memory and I/O Expansion Interface

Six separate linear memory or expansion segments are decoded by the EP7312, two of which can be reserved for two PC Card cards, each interfacing to a separate single CL-PS6700 device. Each segment is 256 Mbytes in size. Two additional segments (i.e., in addition to these six) are dedicated to the on-chip SRAM and the on-chip ROM. The on-chip ROM space and the SRAM space are fully decoded. Beyond this address range the SRAM space is not fully decoded (i.e., any accesses beyond 128 kbyte range get wrapped around to within 128 kbyte range). Any of the six segments are configured to interface to a conventional SRAM-like interface, and can be individually programmed to be 8-, 16-, or 32-bits wide, to support page mode access, and to execute from 1 to 8 wait states for non-sequential accesses and 0 to 3 for burst mode accesses. The zero wait state sequential access feature is designed to support burst mode ROMs. For writable memory devices which use the nMWE pin, zero wait state sequential accesses are not permitted and one wait state is the minimum which should be programmed in the sequential field of the appropriate MEMCFG register. Bus cycles can also be extended using the EXPRDY input signal.

Page mode access is accomplished by setting SQAEN = 1, which enables accesses of the form one random address followed by three sequential addresses, etc., while keeping nCS asserted. These sequential bursts can be up to four words long before nCS is released to allow DMA and refreshes to take place. This can significantly improve bus bandwidth to devices such as ROMs which support page mode. When SQAEN = 0, all accesses to memory are by random access without nCS being de-asserted between accesses. Again nCS is de-asserted after four consecutive accesses to allow DMAS.

Bits 5 and 6 of the SYSCON2 register independently enable the interfaces to the CL-PS6700 (PC Card slot drivers). When either of these interfaces are enabled, the corresponding chip select (nCS[4] and/or nCS[5]) becomes dedicated to that CL-PS6700 interface. The state of SYSCON2 bit 5 determines the function of chip select nCS[4] (i.e., CL-PS6700 interface or standard chip select functionality); bit 6 controls nCS[5] in a similar way. There is no interaction between these bits.

For applications that require a display buffer smaller than 48 kbytes, the on-chip SRAM can be used as the frame buffer.

The width of the boot device can be chosen by selecting values of PE[1] and PE[0] during power on reset. The inputs in Table 11 are latched by the rising edge of nPOR to select the boot option.

PE[1]	PE[0]	Boot Block (nCS[0])
0	0	32-bit
0	1	8-bit
1	0	16-bit
1	1	Undefined

Table 11. Boot Options

2.9 SDRAM Controller

The SDRAM controller in the EP7312 provides all the signals to directly interface to up to four internal banks of SDRAM, and the width of the memory interface is programmable from 16- to 32-bits wide. All internal banks have to be of the same width. The four internal banks that are supported can total together no more than 256 Mbits in size. The signals nSDRAS nSDCAS, and nWE are provided for SDRAM. Two chip selects are provided for supporting up to 2 rows of SDRAMs. The SDRAM devices are put into self-refresh mode when the EP7312 SDRAM controller is put into standby. The SDRAM clock is halted as well.

The controller supports read, write, refresh, precharge, and mode register write requests to the SDRAM. Data is transferred to and from the SDRAM as unbroken quad accesses (either quad word or for 16-bit memory, quad halfword), which is a convenient data packet size for the ARM cache line fills. For the CPU to read smaller than a quad access, the SDRAM controller will discard the extra data. For CPU writes smaller than a quad access, the SDQM pins (SDRAM data byte mask selects) are used to force the SDRAMs to ignore invalid data. For CPU access sizes larger than a quad access, multiple quad accesses are issued to the SDRAM.

The SDRAM controller can access a total memory size of 2-64 Mbytes. Each individual SDRAM should be NEC or compatible SDRAM memory in sizes of 16-256 Mbits, arranged as shown in Table 12 on page 29 and Table 13 on page 30.

The chip selects for the SDRAM devices in row 1 should be connected to nSDCS[0]. For row configurations, those in row 2 should be connected to nSDCS[1].

For 32-bit memory access, four SDQM data byte mask selects are provided by the EP7312 to control individual byte lanes within each row. For 16-bit memory access only, SDQM[0-1] are used. For a 32-bit memory access configuration with each row containing two 16-bit wide SDRAMs, the high order SDRAM should have UDQM (upper SDQM) connected to SDQM[3] and LDQM (lower SDQM) connected to SDQM[2]. The low order SDRAM follows the same convention: UDQM is connected to SDQM[1], and LDQM is connected to SDQM[0].

Memory address line multiplexing is done internally so that the address mapping is contiguous. Table 14 on page 31 indicates how the SDRAM address pins are connected to the EP7312 address pins. Note that small SDRAM devices will not use all of these pins. For example, A12-A11 may not be required. However, the bank select pins BA[0-1], are required by all SDRAMs. Smaller devices may only have one bank, so BA1 may not be needed.

SDRAM Details		Arrangement of SDRAMs (C = # Columns of SDRAM, R = # Rows of SDRAM, D = # of SDRAMs)														
		4 Mbytes			8 Mbytes			16 Mbytes			32 Mbytes			64 Mbytes		
Density (Mbits)	Width (bits)	C	R	D	C	R	D	C	R	D	C	R	D	C	R	D
16	4							8	1	8						
	8				4	1	4									
	16	2	1	2												
64	4													8	1	8
	8										4	1	4	4	2	8
	16							2	1	2	2	2	4			
	32				1	1	1	1	2	2

Table 14. SDRAM Address Pin Connections

2.10 SDRAM Initialization

The SDRAM is initialized in the power-on sequence as follows:

- 1) To stabilize internal circuits when power is applied, a 200 ms pause (or longer) must precede any signal toggling.
- 2) After the pause, all banks must be precharged using the Precharge command (includes the precharge all banks command).
- 3) Once the precharge is complete, and the minimum tRP is satisfied, the mode register can be programmed. After the mode register set cycle, tRSC (2 CLK minimum) pause must be satisfied as well. (Only required for NEC SDRAM)
- 4) Eight or more refresh cycles must be performed.

2.11 CL-PS6700 PC Card Controller Interface

Two of the expansion memory areas are dedicated to supporting up to two CL-PS6700 PC Card controller devices. These are selected by nCS[4] and nCS[5] (must first be enabled by bits 5 and 6 of SYSCON2). For efficient, low power operation, both address and data are carried on the lower 16 bits of the EP7312 data bus.

Accesses are initiated by a write or read from the area of memory allocated for nCS[4] or nCS[5]. The memory map within each of these areas is segmented to allow different types of PC Card accesses to take place, for attribute, I/O, and common memory space. The CL-PS6700 internal registers are memory mapped within the address space as shown in Table 15.

Note: Due to the operating speed of the CL-PS6700, this interface is supported only for processor speeds of 13 and 18 MHz.

A complete description of the protocol and AC timing characteristics can be found in the CL-PS6700 data sheet. A transaction is initiated by an access to the nCS[4] or nCS[5] area. The chip select is asserted, and on the first clock, the upper 10 bits of the PC Card address, along with 6 bits of size, space, and slot information are put out onto the lower 16 bits of the EP7312's data bus. Only word (i.e., 4-byte) and single-byte accesses are supported, and the slot field is hardcoded to 11, since the slot field is defined as a "Reserved field" by the CL-PS6700. The chip selects are used to select the device to be accessed. The space field is made directly from the A26 and A27 CPU address bits, according to the decode shown in Table 16 on page 33. The size field is forced to 11 if a word access is required, or to 00 if a byte access is required. This avoids the need to configure the interface after a reset. On the second clock cycle, the remaining 16 bits of the PC Card address are multiplexed out onto the lower 16 bits of the data bus. If the transaction selected is a CL-PS6700 register transaction, or a write to the PC Card (assuming there is space available in the CL-PS6700's internal write buffer) then the access will continue on the following two clock cycles. During these following two clock cycles the upper and lower halves of the word to be read or written will be put onto the lower 16 bits of the main data bus.

The "ptype" signal on the CL-PS6700s should be connected to the EP7312's WRITE output pin. During PC Card accesses, the polarity of this pin changes, and it becomes low to signify a write and high to signify a read. It is valid with the first half word of the address. During the second half word of the address, it is always forced high to indicate to the CL-PS6700 that the EP7312 has initiated either the write or read.

Access Type	Addresses for CL-PS6700 Interface 1	Addresses for CL-PS6700 Interface 2
Attribute	0x4000.0000–0x43FFFFFF	0x5000.0000– 0x53FFFFFF
I/O	0x4400.0000–0x47FFFFFF	0x5400.0000–0x57FFFFFF
Common memory	0x4800.0000–0x4BFFFFFF	0x5800.0000–0x5BFFFFFF
CL-PS6700 registers	0x4C00.0000–0x4FFFFFFF	0x5C00.0000–0x5FFFFFFF

Table 15. CL-PS6700 Memory Map

Space Field Value	PC CARD Memory Space
00	Attribute
01	I/O
10	Common memory
11	CL-PS6700 registers

Table 16. Space Field Decoding

The PRDY signals from each of the two CL-PS6700 devices are connected to Port B bits 0 and 1, respectively. When the PC CARD1 or PC CARD2 control bits in the SYSCON2 register are de-asserted, these port bits are available for GPIO. When asserted, these port bits are used as the PRDY signals. When the PRDY signal is de-asserted (i.e., low), it indicates that the CL-PS6700 is busy accessing its card. If a PC CARD access is attempted while the device is busy, the PRDY signal will cause the EP7312's CPU to be stalled. The EP7312's CPU will have to wait for the card to become available. DMA transfers to the LCD can still continue in the background during this period of time (as described below). The EP7312 can access the registers in the CL-PS6700, regardless of the state of the PRDY signal. If the EP7312 needs to access the PC CARD via the CL-PS6700, it waits until the PRDY signal is high before initiating a transfer request. Once a request is sent, the PRDY signal indicates if data is available.

In the case of a PC Card write, writes can be posted to the CL-PS6700 device, with the same timing as CL-PS6700 internal register writes. Writes will normally be completed by the CL-PS6700 device independent of the EP7312 processor activity. If a posted write times out, or fails to complete for any other reason, then the CL-PS6700 will issue an interrupt (i.e., a WR_FAIL interrupt). In the case where the CL-PS6700 write buffer is already full, the PRDY signal will be de-asserted (i.e., driven low) and the transaction will be stalled pending an available slot in the buffer. In this case, the EP7312's CPU will be stalled until the write can be posted successfully. While the PRDY signal is de-asserted, the chip select to the CL-PS6700 will be de-asserted and the main bus will be released so that DMA transfers to the LCD controller can continue in the background.

In the case of a PC Card read, the PRDY signal from the CL-PS6700 will be de-asserted until the read data is ready. At this point, it will be reasserted and the access will be completed in the same way as for a register access. In the case of a byte access, only one 16-bit data transfer will be required to complete the access. While the PRDY signal is de-asserted, the chip select to the CL-PS6700 will be de-asserted, and the main bus will be released so that DMA transfers to the LCD controller can continue in the background.

The EP7312 will re-arbitrate for control of the bus when the PRDY signal is reasserted to indicate that the read or write transaction can be completed. The CPU will always be stalled until the PC Card access is completed.

A card read operation may be split into a request cycle and a data cycle, or it may be combined into a single request/data transfer cycle. This depends on whether the data requested from the card is available in the prefetch buffer (internal to the CL-PS6700).

The request portion of the cycle, for a card read, is similar to the request phase for a card write (described above). If the requested data is available in the prefetch buffer, the CL-PS6700 asserts the PRDY signal before the rising edge of the third clock and the EP7312 continues the cycle to read the data. Otherwise, the PRDY signal is de-asserted, and the request cycle is stalled. The EP7312 may then allow the DMA address generator to gain control of the bus, to allow LCD refreshes to continue. When the CL-PS6700 is ready with the data, it asserts the PRDY signal. The EP7312 then arbitrates for the bus and, once the request is granted, the suspended read cycle is resumed. The EP7312 resumes the cycle by asserting the appropriate chip select, and data is transferred on the next two clocks if a word read (one clock if a byte read).

There is no support within the EP7312 for detecting time-outs. The CL-PS6700 device must be programmed to force the cycle to be completed (with invalid data for a read) and then generate an interrupt if a read or write access has timed out (i.e., RD_FAIL or WR_FAIL interrupt). The system software can then determine which access was not successfully completed by reading the status registers within the CL-PS6700.

The CL-PS6700 has support for DMA data transfers. However, DMA is supported only by software emulation because the DMA address generator built into the EP7312 is dedicated to the LCD controller interface. If DMA is enabled within the CL-PS6700, it will assert its PDREQ signal to make a DMA request. This can be connected to one of the EP7312's external interrupts and be used to interrupt the CPU so that the software can service the DMA request under program control.

Each of the CL-PS6700 devices can generate an interrupt PIRQ. Since the PIRQ signal is an open drain on the CL-PS6700 devices, two CL-PS6700 devices may be wired OR'ed to the same interrupt. The circuit can then be connected to one of the EP7312's active low external interrupt sources. On the receipt of an interrupt, the CPU can read the interrupt status registers on the CL-PS6700 devices to determine the cause of the interrupt.

All transactions are synchronized to the EXPCLK output from the EP7312 in 18.432 MHz mode or the external 13 MHz clock. The EXPCLK should be permanently enabled, by setting the EXCKEN bit in the SYSCON1 register, when the CL-PS6700 is used. The reason for this is that the PC Card interface and CL-PS6700 internal write buffers need to be clocked after the EP7312 has completed its bus cycles.

A GPIO signal from the EP7312 can be connected to the PSLEEP pin of the CL-PS6700 devices to allow them to be put into a power saving state before the EP7312 enters the Standby State. It is essential that the software monitor the appropriate status registers within the CL-PS6700s to ensure that there are no pending posted bus transactions before the Standby State is entered. Failure to do this will result in incomplete PC Card accesses.

2.12 Serial Interfaces

In addition to the two UARTs, the EP7312 offers the following serial interfaces shown in Table 17. The inputs / outputs of three of the serial interfaces (DAI, CODEC, and SSI2) are multiplexed onto a single set of external interface pins. If the DAISEL bit of SYSCON3 is low, then either SSI2 or the CODEC interface will be selected to connect to the external pins. When bit 0 of SYSCON2 (SERSEL) is high, then the CODEC is connected to the external pins, when low the master / slave SSI2 is connected to these pins. When the DAISEL bit is set high, the DAI interface is connected to the external pins. On power up, both the DAISEL and SERSEL bits are reset low, thus the master / slave SSI2 will be connected to these pins (and configured for slave mode operation to avoid external drive clashes).

The unique internal names given in Table 17 to each of the serial interfaces will be used to describe each interface.

Pin definition information for the three multiplexed serial interfaces (SSI2, DAI, and CODEC) and the ADC interface is described in Table 18.

Type	Comments	Referred To As	Max. Transfer Speed
SPI / Microwire 1	Master mode only	ADC Interface	128 kbits/s
SPI / Microwire 2	Master / slave mode	SSI2 Interface	512 kbits/s
DAI Interface	CD quality DACs and ADCs	DAI Interface	1.536 Mbits/s
CODEC Interface	Only for use in the PLL clock mode	CODEC Interface	64 kbits/s

Table 17. Serial Interface Options

Pin No. LQFP	External Pin Name	SSI2 Slave Mode (Internal Name)	SSI2 Master Mode	CODEC Internal Name	DAI Internal Name	Strength

Table 18. Serial Pin Assignments

2.13 CODEC Sound Interface

The CODEC interface allows direct connection of a telephony type CODEC to the EP7312. It provides all the necessary clocks and timing pulses. It also performs a parallel to serial conversion or vice versa on the data stream to or from the external CODEC device. The interface is full duplex and contains two separate data FIFOs (16 deep by 8-bits wide, one for the receive data, another for the transmit data).

Data is transferred to or from the CODEC at 64 kbits/s. The data is either written to or read from the appropriate 16-byte FIFO. If enabled, a CODEC interrupt (CSINT) will be generated after every 8 bytes are transferred (FIFO half full/empty). This means the interrupt rate will be every 1 msec, with a latency of 1 msec.

Transmit and receive modes are enabled by asserting high both the CDENRX and CDENTX CODEC enable bits in the SYSCON1 register.

Note: Both the CDENRX and CDENTX enable bits should be asserted in tandem for data to be transmitted or received. The reason for this is that the interrupt generation will occur 1 msec after one of the FIFOs is enabled. For example: If the receive FIFO gets enabled first and the transmit FIFO at a later time, the interrupt will occur 1 msec after the receive FIFO is enabled. After the first interrupt occurs, the receive FIFO will be half full. However, it will not be possible to know how full the transmit FIFO will be since it was enabled at a later time. Thus, it is possible to unintentionally overwrite data already in the transmit FIFO (See Figure 5 on page 37).

After the CDENRX and CDENTX enable bits get asserted, the corresponding FIFOs become enabled. When both FIFOs are disabled, the FIFO status flag CRXFE is set and CTXFF is cleared so that the FIFOs appear empty. Additionally, if the CDENTX bit is low, the PCMOUT output is disabled. Asserting either of the two enable bits causes the sync and interrupt generation logic to become active; otherwise they are disabled to conserve power.

Data is loaded into the transmit FIFO by writing to the CODR register. At the beginning of a transmit cycle, this data is loaded into a shift/load register. Just prior to the byte being transferred out, PCMSYNC goes high for one PCMCLK cycle. Then the data is shifted out serially to PCMOUT, MSB first, (with the MSB valid at the same time PCMSYNC is asserted). Data is shifted on the rising edge of the PCMCLK output.

Receiving of data is performed by taking data in serially through PCMIN, again MSB first, shifting it through the shift/load register and loading the complete byte into the receive FIFO. If there is no data available in the transmit FIFO, then a zero will be loaded into the shift/load register. Input data is sampled on the falling edge of PCMCLK. Data is read from the CODR register.

2.14 Endianness

The EP7312 uses a little endian configuration for internal registers. However, it is possible to connect the device to a big endian external memory system. The big-endian / little-endian bit in the ARM720T control register sets whether the EP7312 treats words in memory as being stored in big endian or little endian format. Memory is viewed as a linear collection of bytes numbered upwards from zero. Bytes 0 to 3 hold the first stored word, bytes 4 to 7 the second, and so on. In the little endian scheme, the lowest numbered byte in a word is considered to be the least significant byte of the word and the highest numbered byte is the most significant. Byte 0 of the memory system should be connected to data lines 7 through 0 (D[7:0]) in this scheme. In the big endian scheme the most significant byte of a word is stored at the lowest numbered byte, and the least significant byte is stored at the highest numbered byte. Therefore, byte 0 of the memory system should be connected to data lines 31 through 24 (D[31:24]). Load and store are the only instructions affected by the Endianness.

Table 19 on page 38 and Table 20 on page 38 demonstrate the behavior of the EP7312 in big and little endian mode, including the effect of performing non-aligned word accesses. The register definition section of this specification defines the behavior of the internal EP7312 registers in the big endian mode in more detail. For further information, refer to *ARM Application Note 61, Big and Little Endian Byte Addressing*.

Table 20. Effect of Endianness on Write Operations

2.15 Internal UARTs (Two) and SIR Encoder

The EP7312 contains two built-in UARTs that offers similar functionality to National Semiconductor's 16C550A device. Both UARTs can support bit rates of up to 115.2 kbits/s and include two 16-byte FIFOs: one for receive and one for transmit.

One of the UARTs (UART1) supports the three modem control input signals CTS, DSR, and DCD. The additional RI input, and RTS and DTR output modem control lines are not explicitly supported but can be implemented using GPIO ports in the EP7312. UART2 has only the RX and TX pins.

UART operation and line speeds are controlled by the UBLCR1 (UART bit rate and line control). Three interrupts can be generated by UART1: RX, TX, and modem status interrupts. Only two can be generated by UART2: RX and TX. The RX interrupt is asserted when the RX FIFO becomes half full or if the FIFO is non-empty for longer than three character length times with no more characters being received. The TX interrupt is asserted if the TX FIFO buffer reaches half empty. The modem status interrupt for UART1 is generated if any of the modem status bits change state. Framing and parity errors are detected as each byte is received and pushed onto the RX FIFO. An overrun error generates an RX interrupt immediately. All error bits can be read from the 11-bit wide data register. The FIFOs can also be programmed to be one byte depth only (i.e., like a conventional 16450 UART with double buffering).

The EP7312 also contains an IrDA (Infrared Data Association) SIR protocol encoder as a post-processing stage on the output of UART1. This encoder can be optionally switched into the TX and RX signals of UART1, so that these can be used to drive an infrared interface directly. If the SIR protocol encoder is enabled, the UART TXD1 line is held in the passive state and transitions of the RXD1 line will have no effect. The IrDA output pin is LEDDRV, and the input from the photodiode is PHDIN. Modem status lines will cause an interrupt (which can be masked) irrespective of whether the SIR interface is being used.

Both the UARTs operate in a similar manner to the industry standard 16C550A. When CTS is deasserted on the UART, the UART does not stop shifting the data. It relies on software to take appropriate action in response to the interrupt generated.

Baud rates supported for both the UARTs are dependent on frequency of operation. When operating from the internal PLL, the interface supports various baud rates from 115.2 kbits/s downwards. The master clock frequency is chosen so that most of the required data rates are obtainable exactly. When operating with a 13.0 MHz external clock source, the baud rates generated will have a slight error, which is less than or equal to 0.75%. The rates (all measured in kbits/s) obtainable from the 13 MHz clock include: 9.6, 19.2, 38, 58, and 115.2. See *UBRLCR1-2 UART1-2 Bit Rate and Line Control Registers* for full details of the available bit rates in the 13 MHz mode.

2.15.1 Digital Audio Interface

The DAI interface provides a high quality digital audio connection to DAI compatible audio devices. The DAI is a subset of I2S audio format that is supported by a number of manufacturers.

The DAI interface produces one 128-bit frame at the audio sample frequency using a bit clock and frame sync signal. Digital audio data is transferred, full duplex, via separate transmit and receive data lines. The bit clock frequency is programmable to 64 fs or 128 fs. The sample frequency (fs) is now programmable from 8-48 KHz using either the on-chip PLL(73.728MHz) or the external 11.2896 Mhz clock.

The DAI interface contains separate transmit and receive FIFO's. The transmit FIFO's are 8 audio samples deep and the receive FIFO's are 12 audio samples deep.

DAI programming centers around the selection of the desired sample frequency (fs). The DAI shares the same output with the CODEC and SSI as shown in Figure 6. All three clocks (MCLK, LRCK, SCLK) become a multiple of the selected sample frequency as illustrated in Figure 7 on page 42. Please see Table 22 on page 42 for the MUX programming matrix.

Figure 6. Portion of the EP7312 Block Diagram Showing Multiplexed Feature

2.15.1.1 DAI Operation

Following reset, the DAI logic is disabled. To enable the DAI, the applications program should first clear the emergency underflow and overflow status bits, which are set following the reset, by writing a 1 to these register bits (in the DAISR register). Next, the DAI control register should be programmed with the desired mode of operation using a word write. The transmit FIFOs can either be “primed” by writing up to eight 16-bit values each, or can be filled by the normal interrupt service routine which handles the DAI FIFOs. Finally, the FIFOs for each channel must be enabled via writes to DAIDR2. At this point, transmission/reception of data begins on the transmit (SDOUT) and receive (SDIN) pins. This is synchronously controlled by either the PLL or the external clock. These fixed frequencies pass through a programmable divider network which will create the appropriate values for SCLK, LRCLK, and MCLK for the desired sample frequency. Examples of sample frequencies are shown in Table 21. Register DAI64Fs enables/disables the bit clock frequency of 64 fs (and the other features as shown in Figure 7 on page 42), but must be complemented by SYSCON3 bit 9 which will enable/disable 128 fs. To enable one rate, you must disable the other.

128 fs Audio Bit Clock (MHz)	64 fs Audio Bit Clock (MHz)	Clock Source (MHz)	Sample Frequency (KHz)	128 fs Divisor (AUDDIV)	64 fs Divisor (AUDDIV)
1.0240	0.5120	73.728	8	36	72
1.4112	0.7056	11.2896	11.025	8	16
1.5360	0.7680	73.728	16	18	36

Table 22. Matrix for Programming the MUX

Abbreviations for Setting Bits

(L) = Low (Cleared)

(H) = High (Set)

(X) = Don't care

Note: To program the MUX, you will need to do the following:

To connect the port to any of the 4 features shown above, a minimum software configuration shown in the table above must be observed. Each register column contains the bit name (bit #) that must be cleared or set for each feature as shown in the column. This table does not complete the programming for each of the features, but allows access to the port only. The interrupt masks for these features will have to be programmed as well.

2.15.1.2 DAI Frame Format

Each DAI frame is 128 bits long and it comprises one audio sample. Of this 128-bit frame, only 32 bits are used for digital audio data. The remaining bits are output as zeros. The LRCK signal is used as a frame synchronization signal. Each transition of LRCK delineates the left and right halves of an audio sample. When LRCK transitions from high-to-low the next 16 bits make up the right side of an audio sample. When LRCK transitions from low-to-high the next 16 bits make up the left side of an audio sample.

2.15.1.3 DAI Signals

- MCLK** oversampled clock. Used as an input to the EP7312 for generating the DAI timing. This signal is also usually used as an input to a DAC/ADC as an oversampled clock. This signal is fixed at 256 times the audio sample frequency.
- SCLK** bit clock. Used as the bit clock input into the DAC/ADC. This signal is fixed at 128 or 64 times the audio sample frequency.
- LRCK** Frame sync. Used as a frame synchronization input to the DAC/ADC. This signal is fixed at the audio sample frequency. This signal is clocked out on the negative going edge of SCLK.
- SDOUT** Digital audio data out. Used for sending playback data to a DAC. This signal is clocked out on the negative going edge of the SCLK output.
- SDIN** Digital audio input. Used for receiving record data from an ADC. This signal is latched by the EP7312 on the positive going edge of SCLK.

2.15.2 ADC Interface — Master Mode Only SSII (Synchronous Serial Interface)

The first synchronous serial interface allows interfacing to the following peripheral devices:

- In the default mode, the device is compatible with the MAXIM MAX148/9 in external clock mode. Similar SPI- or Microwire-compatible devices can be connected directly to the EP7312.
- In the extended mode and with negative-edge triggering selected (the ADCCON and ADCKNSEN bits are set, respectively, in the SYSCON3 register), this device can be interfaced to Analog Devices' AD7811/12 chip using nADCCS as a common RFS/TFS line.
- Other features of the devices, including power management, can be utilized by software and the use of the GPIO pins.

Figure 8. EP7312 Rev B- Digital Audio Interface Timing – MSB / Left Justified format

The clock output frequency is programmable and only active during data transmissions to save power. There are four output frequencies selectable, which will be slightly different depending whether the device is operating in a 13 MHz mode or a 18.432 MHz–73.728 MHz mode (see Table 23). The required frequency is selected by programming the corresponding bits 16 and 17 in the SYSCON1 register. The sample clock (SMPCLK) always runs at twice the frequency of the shift clock (ADCCLK). The output channel is fed by an 8-bit shift register when the ADCCON bit of SYSCON3 is clear. When ADCCON is set, up to 16 bits of configuration command can be sent, as specified in the SYNCIO register. The input channel is captured by a 16-bit shift register. The clock and synchronization pulses are activated by a write to the output shift register. During transfers the SSIBUSY (synchronous serial interface busy) bit in the system status flags register is set. When the transfer is complete and valid data is in the 16-bit read shift register, the SSEOTI interrupt is asserted and the SSIBUSY bit is cleared.

An additional sample clock (SMPCLK) can be enabled independently and is set at twice the transfer clock frequency.

This interface has no local buffering capability and is only intended to be used with low bandwidth interfaces, such as for a touch-screen ADC interface.

2.15.3 Master / Slave SSI2 (Synchronous Serial Interface 2)

A second SPI / Microwire interface with full master / slave capability is provided by the EP7312 data rates in slave mode are theoretically up to 512 kbits/s, full duplex, although continuous operation at this data rate will give an interrupt rate of 2 kHz, which is too fast for many operating systems. This would require a worst-case interrupt response time of less than 0.5 msec and would cause loss of data through TX under-runs and RX overruns.

The interface is fully capable of being clocked at 512 kHz when in slave mode. However, it is anticipated that external hardware will be used to frame the data into packets. Therefore, although the data would be transmitted at a rate of 512 kbits/s, the sustained data rate would in fact only be 85.3 kbits/s (i.e., 1 byte every 750 μsec). At this data rate, the required interrupt rate will be greater than 1 msec, which is acceptable.

There are separate half-word-wide RX and TX FIFOs (16 half-words each) and corresponding interrupts which are generated when the FIFO's are half-full or half-empty as appropriate. The interrupts are called SS2RX and SS2TX, respectively. Register SS2DR is used to access the FIFOs.

SYSCON1 bit 17	SYSCON1 bit 16	13.0 MHz Operation ADCCLK Frequency (kHz)	18.432–73.728 MHz Operation ADCCLK Frequency (kHz)
0	0	4.2	4
0	1	16.9	16
1	0	67.7	64
1	1	135.4	128

Table 23. ADC Interface Operation Frequencies

There are five pins to support this SSI port: SSIRXDA, SSITXFR, SSICLK, SSITXDA, and SSIRXFR. The SSICLK, SSIRXDA, SSIRXFR, and SSITXFR signals are inputs and the SSITXDA signal is an output in slave mode. In the master mode, SSICLK, SSITXDA, SSITXFR, and SSIRXFR are outputs, and SSIRXDA is an input. Master mode is enabled by writing a one to the SS2MAEN bit (SYSCON2[9]). When the master / slave SSI is not required, it can be disabled to save power by writing a zero to the SS2TXEN and the SS2RXEN bits (SYSCON2[4] [7]). When set, these two bits independently enable the transmit and receive sides of the interface.

The master / slave SSI is synchronous, full duplex, and capable of supporting serial data transfers between two nodes. Although the interface is byte-oriented, data is loaded in blocks of two bytes at a time. Each data byte to be transferred is marked by a frame sync pulse, lasting one clock period, and located one clock prior to the first bit being transferred. Direction of the SSI2 ports, in slave and master mode, is shown in Figure 9.

Data on the link is sent MSB first and coincides with an appropriate frame sync pulse, of one clock in duration, located one clock prior to the first data bit sent (i.e., MSB). It is not possible to send data LSB first.

When operating in master mode, the clock frequency is selected to be the same as the ADC interface's (master mode only SSI1) — that is, the frequencies are selected by the same bits 16 and 17 of the SYSCON1 register (i.e., the ADCKSEL bits). Thus, the maximum frequency in master mode is 128 kbits/s. The interface will support continuous transmission at this rate assuming that the OS can respond to the interrupts within 1 msec to prevent over/underruns. The timing diagram for this interface can be found in the *AC Characteristics* section of this document.

Note: To allow synchronization to the incoming slave clock, the interface enable bits will not take effect until one SSICLK cycle after they are written and the value read back from SYSCON2. The enable bits reflect the real status of the enables internally. Hence, there will be a delay before the new value programmed to the enable bits can be read back.

Figure 9. SSI2 Port Directions in Slave and Master Mode

2.15.3.1 Read Back of Residual Data

All writes to the transmit FIFO must be in half-words (i.e., in units of two bytes at a time). On the receive side, it is possible that an odd number of bytes will be received. Bytes are always loaded into the receive FIFO in pairs. Consequently, in the case of a single residual byte remaining at the end of a transmission, it will be necessary for the software to read the byte separately. This is done by reading the status of two bits in the SYSFLG2 register to determine the validity of the residual data. These two bits (RESVAL, RESFRM) are both set high when a residual is valid. RESVAL is cleared on either a new transmission or on reading of the residual bit by software. RESFRM is cleared only on a new transmission. By popping the residual byte into the RX FIFO and then reading the status of these bits it is possible to determine if a residual bit has been correctly read.

Figure 10 illustrates this procedure. The sequence is as follows: read the RESVAL bit, if this is a 0, no action needs to be taken. If this is a 1, then pop the residual byte into the FIFO by writing to the SS2POP location. Then read back the two status bits RESVAL and RESFRM. If these bits read back 01, then the residual byte popped into the FIFO is valid and can be read back from the SS2DR register. If the bits are not 01, then there has been another transmission received since the residual read procedure has been started. The data item that has been popped to the top of the FIFO will be invalid and should be ignored. In this case, the correct byte will have been stored in the most significant byte of the next half-word to be clocked into the FIFO.

Note: All the writes / reads to the FIFO are done word at a time (data on the lower 16 bits is valid and upper 16 bits are ignored).

Software manually pops the residual byte into the RX FIFO by writing to the SS2POP location (the value written is ignored). This write will strobe the RX FIFO write signal, causing the residual byte to be written into the FIFO.

2.15.3.2 Support for Asymmetric Traffic

The interface supports asymmetric traffic (i.e., unbalanced data flow). This is accomplished through separate transmit and receive frame sync control lines. In operation, the receiving node receives a byte of data on the eight clocks following the assertion of the receive frame sync control line. In a similar fashion, the sending node can transmit a byte of data on the eight clocks following the assertion of the transmit frame sync pulse.

Figure 10. Residual Byte Reading

There is no correlation in the frequency of assertions of the RX and TX frame sync control lines (SSITXFR and SSIRXFR). Hence, the RX path may bear a greater data throughput than the TX path, or vice versa. Both directions, however, have an absolute maximum data throughput rate determined by the maximum possible clock frequency, assuming that the interrupt response of the target OS is sufficiently quick.

2.15.3.3 Continuous Data Transfer

Data bytes may be sent / received in a contiguous manner without interleaving clocks between bytes. The frame sync control line(s) are eight clocks apart and aligned with the clock representing bit D0 of the preceding byte (i.e., one bit in advance of the MSB).

2.15.3.4 Discontinuous Clock

In order to save power during the idle times, the clock line is put into a static low state. The master is responsible for putting the link into the Idle State. The Idle State will begin one clock, or more, after the last byte transferred and will resume at least one clock prior to the first frame sync assertion. To disable the clock, the TX section is turned off.

In Master mode, the EP7312 does not support the discontinuous clock.

2.15.3.5 Error Conditions

RX FIFO overflows are detected and conveyed via a status bit in the SYSFLG2 register. This register should be accessed at periodic intervals by the application software. The status register should be read each time the RX FIFO interrupts are generated. At this time the error condition (i.e., overrun flag) will indicate that an error has occurred but cannot convey which byte contains the error. Writing to the SRXEOF register location clears the overrun flag. TX FIFO underflow condition is detected and conveyed via a bit in the SYSFLG2 register, which is accessed by the application software. A TX underflow error is cleared by writing data to be transmitted to the TX FIFO.

2.15.3.6 Clock Polarity

Clock polarity is fixed. TX data is presented on the bus on the rising edge of the clock. Data is latched into the receiving device on the falling edge of the clock. The TX pin is held in a tristate condition when not transmitting.

2.16 LCD Controller with Support for On-Chip Frame Buffer

The LCD controller provides all the necessary control signals to interface directly to a single panel multiplexed LCD. The panel size is programmable and can be any width (line length) from 32 to 1024 pixels in 16-pixel increments. The total video frame buffer size is programmable up to 128 kbytes. This equates to a theoretical maximum panel size of 1024 x 256 pixels in 4 bits-per-pixel mode. The video frame buffer can be located in any portion of memory controlled by the chip selects. Its start address will be fixed at address 0x000.0000 within each chip select. The start address of the LCD video frame buffer is defined in the FBADDR[3-0] register. These bits become the most significant nibble of the external address bus. The default start address is 0xC000.0000 (FBADDR = 0xC). A system built using the on-chip SRAM (OCSR), will then serve as the LCD video frame buffer and miscellaneous data store. The LCD video frame buffer start address should be set to 0x6 in this option. Programming of the register FBADDR is only permitted when the LCD is disabled (this is to avoid possible cycle corruption when changing the register contents while a LCD DMA cycle is in progress). There is no hardware protection to prevent this. It is necessary for the software to disable the LCD controller before reprogramming the FBADDR register. Full address decoding is provided for the OCSR, up to the maximum video frame buffer size programmable into the LCDCON register. Beyond this, the address is wrapped around. The frame buffer start address must not be programmed to 0x4 or 0x5 if either CL-PS6700 interface is in use (PCMEN1 or PCMEN2 bits in the SYSCON2 register are enabled). FBADDR should never be programmed to 0x7 or 0x8, as these are the locations for the on-chip Boot ROM and internal registers.

The screen is mapped to the video frame buffer as one contiguous block where each horizontal line of pixels is mapped to a set of consecutive bytes or words in the video RAM. The video frame buffer can be accessed word wide as pixel 0 is mapped to the LSB in the buffer such that the pixels are arranged in a little endian manner.

The pixel bit rate, and hence the LCD refresh rate, can be programmed from 18.432 MHz to 576 kHz when operating in 18.432–73.728 MHz mode, or 13 MHz to 203 kHz when operating from a 13 MHz clock. The LCD controller is programmed by writing to the LCD control register (LCDCON). The LCDCON register should not be reprogrammed while the LCD controller is enabled.

The LCD controller also contains two 32-bit palette registers, which allow any 4-, 2-, or 1-bit pixel value to be mapped to any of the 15 grayscale values available. The required DMA bandwidth to support a ½ VGA panel displaying 4 bits-per-pixel data at an 80 Hz refresh rate is approximately 6.2 Mbytes/s. Assuming the frame buffer is stored in a 32-bit wide memory, the maximum theoretical bandwidth available is 86 Mbytes/s at 36.864 MHz, or 29.7 Mbytes/s at 13 MHz.

The LCD controller uses a nine stage 32-bit wide FIFO to buffer display data. The LCD controller requests new data when there are five words remaining in the FIFO. This means that for a ½ VGA display at 4 bits-per-pixel and 80 Hz refresh rate, the maximum allowable DMA latency is approximately 3.25 μsec ((5 words x 8 bits/byte) / (640 x 240 x 4bpp x 80 Hz)) = 3.25 μs). The worst-case latency is the total number of cycles from when the DMA request appears to when the first DMA data word actually becomes available at the FIFO. DMA has the highest priority, so it will always happen next in the system. The maximum number of cycles required is 36 from the point at which the DMA request occurs to the point at which the STM is complete, then another 6 cycles before the data actually arrives at the FIFO from the first DMA read. This creates a total of 42 cycles. Assuming the frame buffer is located in 32-bit wide, the worst-case

latency is almost exactly 3.2 μ s, with 13 MHz page mode cycles. With each cycle consuming ~ 77 ns (i.e., 1/13 MHz), the value of 3.2 μ s comes from 42 cycles \times 77 ns/cycle = ~ 3.23 μ s. If 16-bit wide, then the worst-case latency will double. In this case, the maximum permissible display size will be halved, to approximately 320 \times 240 pixels, assuming the same pixel depth and refresh rate has to be maintained. If the frame buffer is to be stored in static memory, then further calculations must be performed. If 18 MHz mode is selected, and 32-bit wide, then the worst-case latency will be 2.26 μ s (i.e., 42 cycles \times 54 ns/cycle). If 36 MHz mode is selected, and 32-bit wide, then the worst-case latency drops down to 1.49 μ s. This calculation is a little more complex for 36 MHz mode of operation. The total number of cycles = (12 \times 4) + 7 = 55. Thus, 55 \times 27 ns = ~ 1.49 μ s.

Figure 11 shows the organization of the video map for all combinations of bits-per-pixel.

The refresh rate is not affected by the number of bits-per-pixel; however the LCD controller fetches twice the data per refresh for 4 bits-per-pixel compared to 2 bits-per-pixel. The main reason for reducing the number of bits-per-pixel is to reduce the power consumption of the memory where the video frame buffer is mapped.

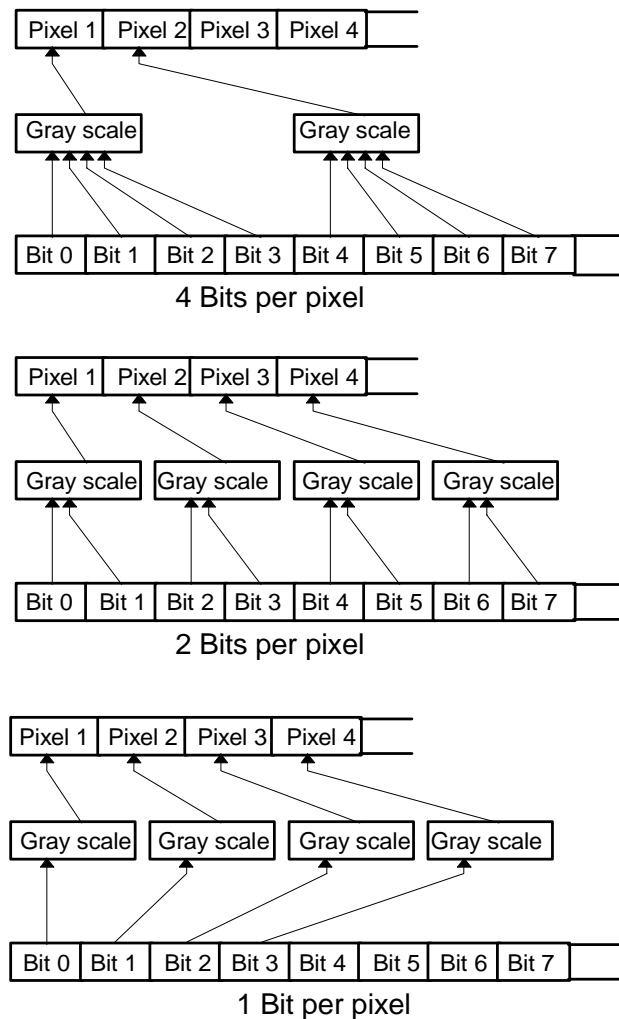

Figure 11. Video Buffer Mapping

2.17 Timer Counters

Two identical timer counters are integrated into the EP7312. These are referred to as TC1 and TC2. Each timer counter has an associated 16-bit read / write data register and some control bits in the system control register. Each counter is loaded with the value written to the data register immediately. This value will then be decremented on the second active clock edge to arrive after the write (i.e., after the first complete period of the clock). When the timer counter under flows (i.e., reaches 0), it will assert its appropriate interrupt. The timer counters can be read at any time. The clock source and mode are selectable by writing to various bits in the system control register. When run from the internal PLL, 512 kHz and 2 kHz rates are provided. When using the 13 MHz external source, the default frequencies will be 541 kHz and 2.115 kHz, respectively. However, only in non-PLL mode, an optional divide by 26 frequency can be generated (thus generating a 500 kHz frequency when using the 13 MHz source). This divider is enabled by setting the OSTB (Operating System Timing Bit) in the SYSCON2 register (bit 12). When this bit is set high to select the 500 kHz mode, the 500 kHz frequency is routed to the timers instead of the 541 kHz clock. This does not affect the frequencies derived for any of the other internal peripherals.

The timer counters can operate in two modes: free running or pre-scale.

2.17.1 Free Running Mode

In the free running mode, the counter will wrap around to 0xFFFF when it under flows and it will continue to count down. Any value written to TC1 or TC2 will be decremented on the second edge of the selected clock.

2.17.2 Prescale Mode

In the prescale mode, the value written to TC1 or TC2 is automatically re-loaded when the counter under flows. Any value written to TC1 or TC2 will be decremented on the second edge of the selected clock. This mode can be used to produce a programmable frequency to drive the buzzer (i.e., with TC1) or generate a periodic interrupt. The formula is $F = (500 \text{ kHz}) / (n+1)$.

2.18 Real Time Clock

The EP7312 contains a 32-bit Real Time Clock (RTC). This can be written to and read from in the same way as the timer counters, but it is 32 bits wide. The RTC is always clocked at 1 Hz, generated from the 32.768 kHz oscillator. It also contains a 32-bit output match register, this can be programmed to generate an interrupt when the time in the RTC matches a specific time written to this register. The RTC can only be reset by an nPOR cold reset. Because the RTC data register is updated from the 1 Hz clock derived from the 32 kHz source, which is asynchronous to the main memory system clock, the data register should always be read twice to ensure a valid and stable reading. This also applies when reading back the RTCDIV field of the SYSCON1 register, which reflects the status of the six LSBs of the RTC counter.

2.18.1 Characteristics of the Real Time Clock Interface

When connecting a crystal to the RTC interface pins (i.e., RTCIN and RTCOUT), the crystal and circuit should conform to the following requirements:

- The 32.768 kHz frequency should be created by the crystals fundamental tone (i.e., it should be a fundamental mode crystal)
- A start-up resistor is not necessary, since one is provided internally.
- Start-up loading capacitors may be placed on each side of the external crystal and ground. Their value should be in the range of 10 pF. However, their values should be selected based upon the crystal specifications. The total sum of the capacitance of the traces between the EP7312's clock pins, the capacitors, and the crystal leads should be subtracted from the crystal's specifications when determining the values for the loading capacitors.
- The crystal should have a maximum 5 ppm frequency drift over the chip's operating temperature range.
- The voltage for the crystal must be $2.5 \text{ V} \pm 0.2 \text{ V}$.

Alternatively, a digital clock source can be used to drive the RTCIN pin of the EP7312. With this approach, the voltage levels of the clock source should match that of the V_{DD} supply for the EP7312's pads (i.e., the supply voltage level used to drive all of the non- V_{DD} core pins on the EP7312) (i.e., RTCOUT). The output clock pin should be left floating.

2.19 Dedicated LED Flasher

The LED flasher feature enables an external pin (PD[0] / LEDFLSH) to be toggled at a programmable rate and duty ratio, with the intention that the external pin is connected to an LED. This module is driven from the RTC's 32.768 kHz oscillator and works in all running modes because no CPU intervention is needed once its rate and duty ratio have been configured (via the LEDFLSH register). The LED flash rate period can be programmed for 1, 2, 3, or 4 seconds. The duty ratio can be programmed such that the mark portion can be 1/16, 2/16... 16/16 of the full cycle. The external pin can provide up to 4 mA of drive current.

2.20 Two PWM Interfaces

Two Pulse Width Modulator (PWM) duty ratio clock outputs are provided by the EP7312. When the device is operating from the internal PLL, the PWM will run at a frequency of 96 kHz. These signals are intended for use as drives for external DC-to-DC converters in the Power Supply Unit (PSU) subsystem. External input pins that would normally be connected to the output from comparators monitoring the external DC-to-DC converter output are also used to enable these clocks. These are the FB[0-1] pins. The duty ratio (and hence PWMs on time) can be programmed from 1 pulse in 16 pulses to 15 in 16. The sense of the PWM drive signal (active high or low) is determined by latching the state of this drive signal during power on reset (i.e., a pull-up on the drive signal will result in a active low drive output, and visa versa). This allows either positive or negative voltages to be generated by the external DC-to-DC converter. PWMs are disabled by writing zeros into the drive ratio fields in the PMPCON Pump Control register.

Note: To maximize power savings, the drive ratio fields should be used to disable the PWMs, instead of the FB pins. The clocks that source the PWMs are disabled when the drive ratio fields are zeroed.

2.21 Boundary Scan

IEEE 1149.1 compliant JTAG is provided with the EP7312. Table 24 shows what JTAG instructions are supported in the EP7312.

Instruction	Code	Description
EXTEST	0000	Places the selected scan chain in test mode.
SCAN_N	0010	Connects the Scan Path Register between TDI and TDO
SAMPLE / PRE-LOAD	0011	NOTE: This instruction is included for product testing only and should never be used.
IDCODE	1110	Connects the ID register between TDI and TDO
BYPASS	1111	Connects a 1-bit shift register bit TDI and TDO

Table 24. Instructions Supported in JTAG Mode

Note: The INTEST function will not be supported for the EP7312.

Additional user-defined instructions exist, but these are not relevant to board-level testing. For further information please refer to the *ARM DDI 0087E ARM720T Data Sheet*.

As there are additional scan-chains within the ARM720T processor, it is necessary to include a scan-chain select function — shown as SCAN_N in Table 24. To select a particular scan chain, this function must be input to the TAP controller, followed by the 4-bit scan chain identification code. The identification code for the boundary scan chain is 0011.

Note that it is only necessary to issue the SCAN_N instruction if the device is already in the JTAG mode. The boundary scan chain is selected as the default on test-logic reset and any of the system resets.

The contents of the device ID-register for the EP7312 are shown in Figure 12. This is equivalent to 0x0F0F.0F0F. Note this is the ID-code for the ARM720T processor.

Version	Part number	Manufacturer ID
0 0 0 0	1 1 1 1 0 0 0 0 1 1 1 1 0 0 0 0	1 1 1 1 0 0 0 0 1 1 1 1

Figure 12. Device ID Register

2.22 In-Circuit Emulation

2.22.1 Introduction

EmbeddedICE™ is an extension to the architecture of the ARM family of processors, and provides the ability to debug cores that are deeply embedded into systems. It consists of three parts:

- A set of extensions to the ARM core
- The EmbeddedICE macrocell, which provides external access to the extensions
- The EmbeddedICE interface, which provides communication between the host computer and the EmbeddedICE macrocell

The EmbeddedICE macrocell is programmed, in a serial fashion, through the TAP controller on the ARM via the JTAG interface. The EmbeddedICE macrocell is by default disabled to minimize power usage, and must be enabled at boot-up to support this functionality.

2.22.2 Functionality

The ICEBreaker module consists of two real-time watchpoint units together with a control and status register. One or both of the units can be programmed to halt the execution of the instructions by the ARM processor. Execution is halted when either a match occurs between the values programmed into the ICEBreaker and the values currently appearing on the address bus, data bus, and the various control signals. Any bit can be masked to remove it from the comparison. Either unit can be programmed as a watchpoint (monitoring data accesses) or a breakpoint (monitoring instruction fetches).

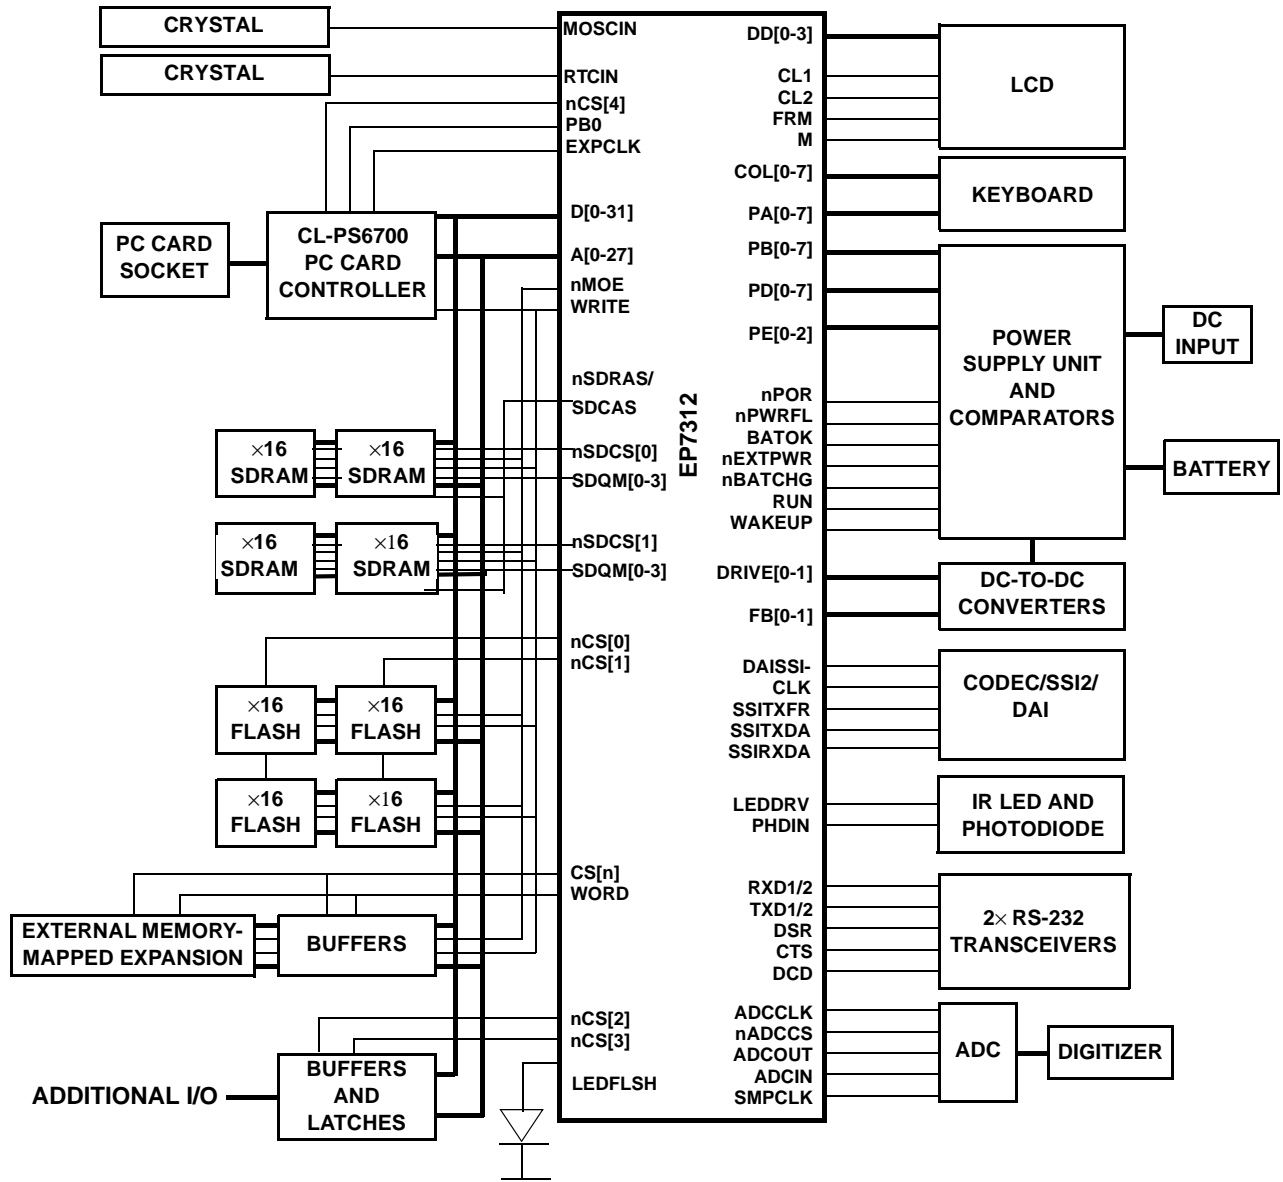

Using one of these watchpoint units, an unlimited number of software breakpoints (in RAM) can be supported by substitution of the actual code.

Note: The EXTERN[1:0] signals from the ICEBreaker module are not wired out in this device. This mechanism is used to allow watchpoints to be dependent on an external event. This behavior can be emulated in software via the ICEBreaker control registers.

A more detailed description is available in the *ARM Software Development Toolkit User Guide and Reference Manual*. The ICEBreaker module and its registers are fully described in the *ARM7TDMI Data Sheet*.

2.23 Maximum-Configured EP7312-Based System

A maximum configured system using the EP7312 is shown in Figure 13 on page 54. This system assumes all of the SDRAMs and ROMs are 16-bit wide devices. The keyboard may be connected to more GPIO bits than shown to allow greater than 64 keys, however these extra pins will not be wired into the WAKE-UP pin functionality.

NOTE: A system can only use one of the following peripheral interfaces at any given time: SSI2, CODEC, or DAI.

Figure 13. A Maximum EP7312 Based System

2.24 I/O Buffer Characteristics

All I/O buffers on the EP7312 are CMOS threshold input bidirectional buffers except the oscillator and power pads. For signals that are nominally inputs, the output buffer is only enabled during pin test mode. All output buffers are three stated during system (hi-Z) test mode. All buffers have a standard CMOS threshold input stage (apart from the Schmitt-triggered inputs) and CMOS slew-rate- controlled output stages to reduce system noise. Table 25 defines the I/O buffer output characteristics which will apply across the full range of temperature and voltage (i.e., these values are for 3.3 V, +70°C).

All propagation delays are specified at 50% V_{DD} to 50% V_{DD} , all rise times are specified as 10% V_{DD} to 90% V_{DD} and all fall times are specified as 90% V_{DD} to 10% V_{DD} .

Buffer Type	Drive Current	Propagation Delay (Max)	Rise Time (Max)	Fall Time (Max)	Load
I/O strength 1	±4 mA	7	14	14	50 pF
I/O strength 2	±12 mA	5	6	6	50 pF

Table 25. I/O Buffer Output Characteristics

3. TEST MODES

The EP7312 supports a number of hardware activated test modes, these are activated by the pin combinations shown in Table 26. All latched signals will only alter test modes while NPOR is low, their state is latched on the rising edge of NPOR. This allows these signals to be used normally during various test modes.

Within each test mode, a selection of pins is used as multiplexed outputs or inputs to provide / monitor the test signals unique to that mode.

Test Mode	Latched nMEDCHG	Latched PE[0]	Latched PE[1]	Latched nURESET	nTEST[0]	nTEST[1]
Normal operation (32-bit boot)	1	0	0	X	1	1
Normal operation (8-bit boot)	1	1	0	X	1	1
Normal operation (16-bit boot)	1	0	1	X	1	1
13 Mhz divided by 4	1	1	1	X	1	1
Alternative test ROM boot	0	X	X	X	1	1
Oscillator / PLL bypass	X	X	X	X	1	0
Functional Test (EPB)	0	X	X	1	0	1
Oscillator / PLL test mode	X	X	X	0	0	1
ICE Mode	X	X	X	1	0	0
System test (all HiZ)	X	X	X	0	0	0

Table 26. EP7312 Hardware Test Modes

3.1 Oscillator and PLL Bypass Mode

This mode is selected by $nTEST[0] = 1$, $nTEST[1] = 0$.

In this mode, all the internal oscillators and PLL are disabled, and the appropriate crystal oscillator pins become the direct external oscillator inputs bypassing the oscillator and PLL. MOSCIN must be driven by a 36.864 MHz clock source and RTCIN by a 32.768 kHz source.

3.2 Oscillator and PLL Test Mode

This mode is selected by $nTEST[0] = 0$, $nTEST[1] = 1$, Latched $nURESET = 0$

This test mode will enable the main oscillator and will output various buffered clock and test signals derived from the main oscillator, PLL, and 32 kHz oscillator. All internal logic in the EP7312 will be static and isolated from the oscillators, with the exception of the 6-bit ripple counter used to generate 576 kHz and the Real Time Clock divide chain. Port A is used to drive the inputs of the PLL directly, and the various clock and PLL outputs are monitored on the COL pins. Table 27 defines the EP7312 signal pins used in this test mode. This mode is only intended to allow test of the oscillators and PLL. Note that these inputs are inverted before being passed to the PLL to ensure that the default state of the port (all zero) maps onto the correct default state of the PLL ($TSEL = 1$, $XTALON = 1$, $PLLON = 1$, $D0 = 0$, $D1 = 1$, $PLLBP = 0$). This state will produce the correct frequencies as shown in Table 27. Any other combinations are for testing the oscillator and PLL and should not be used in-circuit.

Signal	I/O	Pin	Function
TSEL	I	PA5	PLL test mode
XTLON	I	PA4	Enable to oscillator circuit
PLLON	I	PA3	Enable to PLL circuit
PLLBP	I	PA0	Bypasses PLL
RTCCLK	O	COL0	Output of RTC oscillator
CLK1	O	COL1	1 Hz clock from RTC divider chain
OSC36	O	COL2	36 MHz divided PLL main clock
CLK576K	O	COL4	576 KHz divided from above
VREF	O	COL6	Test clock output for PLL

Table 27. Oscillator and PLL Test Mode Signals

3.3 Debug / ICE Test Mode

This mode is selected by $nTEST0 = 0$, $nTEST1 = 0$, Latched $nURESET = 1$.

Selection of this mode enables the debug mode of the ARM720T. By default, this is disabled which saves approximately 3% on power.

3.4 Hi-Z (System) Test Mode

This mode selected by $nTEST0 = 0$, $nTEST1 = 0$, Latched $nURESET = 0$.

This test mode asynchronously disables all output buffers on the EP7312. This has the effect of removing the EP7312 from the PCB so that other devices on the PCB can be in-circuit tested. The internal state of the EP7312 is not altered directly by this test mode.

3.5 Software Selectable Test Functionality

When bit 11 of the SYSCON register is set high, internal peripheral bus register accesses are output on the main address and data buses as though they were external accesses to the address space addressed by $nCS[5]$. Hence, $nCS[5]$ takes on a dual role, it will be active as the strobe for internal accesses and for any accesses to the standard address range for $nCS[5]$. Additionally, in this mode, the internal signals shown in Table 28 are multiplexed out of the device on port pins.

This test is not intended to be used when LCD DMA accesses are enabled. This is due to the fact that it is possible to have internal peripheral bus activity simultaneously with a DMA transfer. This would cause bus contention to occur on the external bus.

The “Waited clock to CPU” is an internally ANDed source that generates the actual CPU clock. Thus, it is possible to know exactly when the CPU is being clocked by viewing this pin. The signals $nFIQ$ and $nIRQ$ are the two output signals from the internal interrupt controller. They are input directly into the ARM720T processor.

Signal	I/O	Pin	Function
CLK	O	PE0	Waited clock to CPU
$nFIQ$	O	PE1	$nFIQ$ interrupt to CPU
$nIRQ$	O	PE2	$nIRQ$ interrupt to CPU

Table 28. Software Selectable Test Functionality

Part II: Pin and Register Reference

4. PIN DESCRIPTIONS

Table 29 describes the function of all external signals to the EP7312. Note that all output signals and all I/O pins (when acting as outputs) are three stateable. This is to enable the Hi-Z test modes to be supported.

4.1 External Signal Functions

Function	Signal Name	Signal	Description
Data bus	D[0-31]	I/O	32-bit system data bus for memory, SDRAM, and I/O interface
Address bus	A[0-14]	I/O	15 bits of system byte address during memory and expansion cycles
	A[13-27] / DRA[0-14]	I/O	DRA[0-14] are multiplexed with A[13-27], offering additional power savings since the lightest loading is expected on the high order ROM address lines. Whenever the EP7312 is in the Standby State, the external address and data buses are driven low. The RUN signal is used internally to force these buses to be driven low. This is done to prevent peripherals that are powered-down from draining current. Also, the internal peripheral's signals get set to their Reset State.

Table 29. External Signal Functions

Function	Signal Name	Signal	Description											
Memory Inter- face	BA[0-1]/ A[13-14]	I/O	SDRAM bank select pins											
	nMOE/nSDCAS	O	ROM expansion OP enable/ SDRAM CAS control signal											
	nMWE/nSDWE	O	ROM expansion write enable/ SDRAM write enable control signal											
	nCS[0-3]	O	Chip select; active low, SRAM-like chip selects for expansion											
	nCS[4-5]	O	Chip select; active low, CS for expansion or for CL-PS6700 select											
	SDQM[0-3]	I/O	Data input/output masks											
	EXPRDY	I	Expansion port ready; external expansion devices drive this low to extend the bus cycle. This is used to insert wait states for an external bus cycle.											
	WRITE/ nSDRAS	O	Transfer Direction/SDRAM RAS control signal											
WORD / HALFWORD	O	To do write accesses of different sizes Word and Half-Word must be externally decoded. The encoding of these signals is as follows: <table border="1" data-bbox="782 873 1351 1121"> <thead> <tr> <th>Access Size</th> <th>Word</th> <th>Half-Word</th> </tr> </thead> <tbody> <tr> <td>Word</td> <td>1</td> <td>0</td> </tr> <tr> <td>Half-Word</td> <td>0</td> <td>1</td> </tr> <tr> <td>Byte</td> <td>0</td> <td>0</td> </tr> </tbody> </table> <p>The core will generate an address. When doing a read, the ARM core will select the appropriate byte channels. When doing a write, the correct bytes will have to be enabled depending on the above signals and the least significant bits of the address bus.</p> <p>The ARM architecture does not support unaligned accesses. For a read using x 32 memory, it is assumed that you will ignore bits 1 and 0 of the address bus and perform a word read (or in power critical systems decode the relevant bits depending on the size of the access). If an unaligned read takes place, the core will rotate the resulting data in the register. For more information on this behavior see the LDR instruction in the ARM7TDMI data sheet.</p>	Access Size	Word	Half-Word	Word	1	0	Half-Word	0	1	Byte	0	0
Access Size	Word	Half-Word												
Word	1	0												
Half-Word	0	1												
Byte	0	0												

Table 29. External Signal Functions (cont.)

Function	Signal Name	Signal	Description
External Clock	EXPCLK	I/O	Expansion clock rate is the same as the CPU clock for 13 MHz and 18 MHz. It runs at 36.864 MHz for 36,49 and 74 MHz modes; in 13 MHz mode this pin is used as the clock input.
Interrupts	nMEDCHG / nBROM	I	Media changed input; active low, deglitched. Used as a general purpose FIQ interrupt during normal operation. It is also used on power up to configure the processor to either boot from the internal Boot ROM, or from external memory. When low, the chip will boot from the internal Boot ROM.
	nEXTFIQ	I	External active low fast interrupt request input
	EINT[3]	I	External active high interrupt request input
	nEINT[1-2]	I	Two general purpose, active low interrupt inputs
Power Management	nPWRFL	I	Power fail input; active low, deglitched input to force system into the Standby State
	BATOK ¹	I	Main battery OK input; falling edge generates a FIQ, a low level in the Standby State inhibits system start up; deglitched input
	nEXTPWR	I	External power sense; must be driven low if the system is powered by an external source
	nBATCHG ¹	I	New battery sense; driven low if battery voltage falls below the "no-battery" threshold; it is a deglitched input

Table 29. External Signal Functions (cont.)

Function	Signal Name	Signal	Description
State Control	nPOR	I	Power-on reset input. This signal is not deglitched. When active it completely resets the entire system, including all the RTC registers. Upon power-up, the signal must be held active low for a minimum of 100 μ sec after V_{DD} has settled. During normal operation, nPOR needs to be held low for at least one clock cycle of the selected clock speed (i.e., when running at 13 MHz, the pulse width of nPOR needs to be > 77 nsec). Note that nURESET, RUN/CLKEN, TEST[0], TEST[1], PE[0], PE[1], PE[2], DRIVE[0], DRIVE[1], DD[0], DD[1], DD[2], and DD[3] are all latched on the rising edge of nPOR.
	RUN/CLKEN	O	This pin is programmed to either output the RUN signal or the CLKEN signal. The CLKENSL bit is used to configure this pin. When RUN is selected, the pin will be high when the system is active or idle, low while in the Standby State. When CLKEN is selected, the pin will only be driven low when in the Standby State (For RUN, see Table 31 on page 66).
	WAKEUP ¹	I	Wake up is a deglitched input signal. It must also be held high for at least 125 μ sec to guarantee its detection. Once detected it forces the system into the Operating State from the Standby State. It is only active when the system is in the Standby State. This pin is ignored when the system is in the Idle or Operating State. It is used to wakeup the system after first power-up, or after software has forced the system into the Standby State. WAKEUP will be ignored for up to two seconds after nPOR goes HIGH. Therefore, the external WAKEUP logic must be designed to allow it to rise and stay HIGH for at least 125 usec, two seconds after nPOR goes HIGH.
	nURESET ¹	I	User reset input; active low deglitched input from user reset button. This pin is also latched upon the rising edge of nPOR and read along with the input pins nTEST[0-1] to force the device into special test modes. nURESET does not reset the RTC.
DAI, CODEC or SSI2 Interface (See Table 30 on page 66 for pin assignment and direction following multiplexing)	SSICLK	I/O	DAI/CODEC/SSI2 clock signal
	SSITXFR	I/O	DAI/CODEC/SSI2 serial data output frame/synchronization pulse output
	SSITXDA	O	DAI/CODEC/SSI2 serial data output
	SSIRXDA	I	DAI/CODEC/SSI2 serial data input
	SSIRXFR	I/O	SSI2 serial data input frame/synchronization pulse DAI external clock input

Table 29. External Signal Functions (cont.)

Function	Signal Name	Signal	Description
ADC Interface (SSI1)	ADCCLK	O	Serial clock output
	nADCCS	O	Chip select for ADC interface
	ADCOUT	O	Serial data output
	ADCIN	I	Serial data input
	SMPCLK	O	Sample clock output
IrDA and RS232 Interfaces	LEDDR	O	Infrared LED drive output (UART1)
	PHDIN	I	Photo diode input (UART1)
	TXD[1-2]	O	RS232 UART1 and 2 TX outputs
	RXD[1-2]	I	RS232 UART1 and 2 RX inputs
	DSR	I	RS232 DSR input
	DCD	I	RS232 DCD input
	CTS	I	RS232 CTS input
LCD	DD[0-3]	I/O	LCD serial display data; pins can be used on power up to read the ID of some LCD modules (See Table 31 on page 66).
	CL[1]	O	LCD line clock
	CL[2]	O	LCD pixel clock
	FRM	O	LCD frame synchronization pulse output
	M	O	LCD AC bias drive
Keyboard & Buzzer drive LED Flasher	COL[0-7]	O	Keyboard column drives (SYSCON1)
	BUZ	O	Buzzer drive output (SYSCON1)
	PD[0]/LEDFLSH	O	LED flasher driver — multiplexed with Port D bit 0. This pin can provide up to 4 mA of drive current.

Table 29. External Signal Functions (cont.)

Function	Signal Name	Signal	Description
General Purpose I/O	PA[0-7]	I/O	Port A I/O (bit 6 for boot clock option, bit 7 for CL-PS6700 PRDY input); also used as keyboard row inputs
	PB[0] / PRDY1 PB[1] / PRDY2 PB[2-7]	I/O	Port B I/O. All eight Port B bits can be used as GPIOs. When the PC CARD1 or 2 control bits in the SYSCON2 register are de-asserted, PB[0] and PB[1] are available for GPIO. When asserted, these port bits are used as the PRDY signals for connected CL-PS6700 PC Card Host Adapter devices.
	PD[0-5]	I/O	Port D I/O
	PD[6-7]/ SDQM [0-1]	I/O	Port D I/O, byte mask select.
	PE[0]/ BOOTSEL[0]	I/O	Port E I/O (3 bits only). Can be used as general purpose I/O during normal operation.
	PE[1] / BOOTSEL[1]	I/O	During power-on reset, PE[0] and PE[1] are inputs and are latched by the rising edge of nPOR to select the memory width that the EP7312 will use to read from the boot code storage device (i.e., external 8-bit-wide FLASH bank).
	PE[2] / CLKSEL	I/O	During power-on reset, PE[2] is latched by the rising edge of nPOR to select the clock mode of operation (i.e., either the PLL or external 13 MHz clock mode).
PWM Drives	DRIVE[0-1]	I/O	PWM drive outputs. These pins are inputs on power up to determine what polarity the output of the PWM should be when active. Otherwise, these pins are always an output (See Table 31 on page 66).
	FB[0-1]	I	PWM feedback inputs
Boundary Scan	TDI	I	JTAG data in
	TDO	O	JTAG data out
	TMS	I	JTAG mode select
	TCLK	I	JTAG clock
	nTRST	I	JTAG async reset
Test	nTEST[0-1]	I	Test mode select inputs. These pins are used in conjunction with the power-on latched state of nURESET to select between the various device test models.
Oscillators	MOSCIN MOSCOUT	I O	Main 3.6864 MHz oscillator for 18.432 MHz–73.728 MHz PLL
	RTCIN RTCOUT	I O	Real Time Clock 32.768 kHz oscillator
No Connects	N/C		No connects should be left as no connects; do not connect to ground

Table 29. External Signal Functions (cont.)

All deglitched inputs are via the 16.384 kHz clock. Each deglitched signal must be held active for at least two clock periods. Therefore, the input signal must be active for at least ~125 μ s to be detected cleanly.

Note: The RTC crystal must be populated for the device to function properly.

4.2 SSI / CODEC / DAI Pin Multiplexing

SSI2	CODEC	DAI	Direction	Strength
SSICLK	PCMCLK	SCLK	I/O	1
SSITXFR	PCMSYNC	LRCK	I/O	1
SSITXDA	PCMOUT	SDOUT	Output	1
SSIRXDA	PCMIN	SDIN	Input	
SSIRXFR	p/u*	MCLK	I/O	1

* p/u = use an ~10 k pull-up

Table 30. SSI/CODEC/DAI Pin Multiplexing

The selection between SSI2 and the CODEC is controlled by the state of the SERSEL bit in SYSCON2 (See *SYSCON2 System Control Register 2*). The choice between the SSI2, CODEC, and the DAI is controlled by the DAISEL bit in SYSCON3 (See *SYSCON3 System Control Register 3*).

4.3 Output Bi-Directional Pins

RUN	The RUN pin is looped back in to skew the address and data bus from each other.
Drive [0-1]	Drive 0 and 1 are looped back in on power up to determine what polarity the output of the PWM should be when active.
DD[0-3]	DD[0-3] are looped back in on power up to enable the reading of the ID of some LCD modules.

Table 31. Output Bi-Directional Pins

Note: The above output pins are implemented as bi-directional pins to enable the output side of the pad to be monitored and hence provide more accurate control of timing or duration.

5. EP7312 MEMORY MAP

The lower 2 GByte of the address space is allocated to memory. The 0.5 GByte of address space from 0xC000.0000 to 0xDFFF.FFFF is allocated to SDRAM. The 1.5 GByte, less 8 kbytes for internal registers, is not accessible in the EP7312. The MMU in the EP7312 should be programmed to generate an abort exception for access to this area.

Internal peripherals are addressed through a set of internal memory locations from hex address 0x8000.0000 to 0x8000.3FFF. These are known as the internal registers in the EP7312. In Table 32, the memory map from 0x8000.0000 to 0x8000.1FFF contains registers that are compatible with the CL-PS7111. These were included for backward compatibility and are referred to as old internal registers.

Table 32 also shows how the 4-Gbyte address range of the ARM720T processor (as configured within this chip) is mapped in the EP7312. The memory map shown assumes that two CL-PS6700 PC Card controllers are connected. If this functionality is not required, then the nCS[4] and nCS[5] memory is available. The external boot ROM is not fully decoded (i.e., the boot code will repeat within the 256-Mbyte space from 0x7000.0000 to 0x8000.0000). See Table 11 on page 27 for the memory map when booted from on-chip boot ROM. The SRAM is fully decoded up to a maximum size of 128 kbytes. Access to any location above this range will be wrapped to within the range.

Address	Contents	Size
0xF000.0000	Reserved	256 Mbytes
0xE000.0000	Reserved	256 Mbytes
0xD000.0000	Reserved	256 Mbytes
0xC000.0000	SDRAM	64 Mbytes
0x8000.4000	Unused	~1 Gbyte
0x8000.2000	Internal registers (new)	8 kbytes
0x8000.0000	Internal registers (old) (from CL-PS7111)	8 kbytes
0x7000.0000	Boot ROM (nCS[7])	128 bytes
0x6000.0000	SRAM (nCS[6])	48 kbytes
0x5000.0000	PCMCIA-1 (nCS[5])	4 x 64 Mbytes
0x4000.0000	PCMCIA-0 (nCS[4])	4 x 64 Mbytes
0x3000.0000	Expansion (nCS[3])	256 Mbytes
0x2000.0000	Expansion (nCS[2])	256 Mbytes
0x1000.0000	ROM Bank 1 (nCS[1])	256 Mbytes
0x0000.0000	ROM Bank 0 (nCS[0])	256 Mbytes

Table 32. EP7312 Memory Map in External Boot Mode

6. REGISTER DESCRIPTIONS

6.1 Internal Registers

Table 33 on page 69 shows the Internal Registers of the EP7312 that are compatible with the EP7211 when the CPU is configured to a little endian memory system. Table 34 on page 72 shows the differences that occur when the CPU is configured to a big endian memory system for byte-wide access to Ports A, B, and D. All the internal registers are inherently little endian (i.e., the least significant byte is attached to bits 7 to 0 of the data bus). Hence, the system Endianness affects the addresses required for byte accesses to the internal registers, resulting in a reversal of the byte address required to read / write a particular byte within a register. Note that the internal registers have been split into two groups – the “old” and the “new”. The old ones are the same as that used in EP7211 and are there for compatibility. The new registers are for accessing the additional functionality of the DAI interface and the LED flasher.

There is no effect on the register addresses for word accesses. Bits A[0-1] of the internal address bus are only decoded for Ports A, B, and D (to allow read / write to individual ports). For all other registers, bits A[0-1] are not decoded, so that byte reads will return the whole register contents onto the EP7312’s internal bus, from where the appropriate byte (according to the endianness) will be read by the CPU. To avoid the additional complexity, it is preferable to perform all internal register accesses as word operations, except for ports A to D which are explicitly designed to operate with byte accesses, as well as with word accesses.

An 8 k segment of memory in the range 0x8000.0000 to 0x8000.3FFF is reserved for internal use in the EP7312. Accesses in this range will not cause any external bus activity unless debug mode is enabled. Writes to bits that are not explicitly defined in the internal area are legal and will have no effect. Reads from bits not explicitly defined in the internal area are legal but will read undefined values. All the internal addresses should only be accessed as 32-bit words and are always on a word boundary, except for the PIO port registers, which can be accessed as bytes. Address bits in the range A[0-5] are not decoded (except for Ports A–D), this means each internal register is valid for 64 bytes (i.e., the SYSFLG1 register appears at locations 0x8000.0140 to 0x8000.017C). There are some gaps in the register map for backward compatibility reasons, but registers located next to a gap are still only decoded for 64 bytes.

The GPIO port registers are byte-wide and can be accessed as a word but not as a half-word. These registers additionally decode A[0-1]. All addresses are in hexadecimal notation.

Note: All byte-wide registers should be accessed as words (except Port A to Port D registers, which are designed to work in both word and byte modes).

All registers bit alignment starts from the LSB of the register (i.e., they are all right shift justified). The registers which interact with the 32 kHz clock or which could change during readback (i.e., RTC data registers, SYSFLG1 register (lower 6-bits only), the TC1D and TC2D data registers, port registers, and interrupt status registers), should be read twice and compared to ensure that a stable value has been read back.

All internal registers in the EP7312 are reset (cleared to zero) by a system reset (i.e., nPOR, nRESET, or nPWRFL signals becoming active), and the Real Time Clock data register (RTCDR) and match register (RTCMR), which are only reset by nPOR becoming active. This ensures that the system time preserved through a user reset or power fail condition. In the following register descriptions, little endian is assumed.

Address	Name	Default	RD/WR	Size	Comments
0x8000.0000	PADR	0	RW	8	Port A data register
0x8000.0001	PBDR	0	RW	8	Port B data register
0x8000.0002	—		—	8	Reserved
0x8000.0003	PDDR	0	RW	8	Port D data register
0x8000.0040	PADDR	0	RW	8	Port A data direction register
0x8000.0041	PBDDR	0	RW	8	Port B data direction register
0x8000.0042	—		—	8	Reserved
0x8000.0043	PDDDR	0	RW	8	Port D data direction register
0x8000.0080	PEDR	0	RW	3	Port E data register
0x8000.00C0	PEDDR	0	RW	3	Port E data direction register
0x8000.0100	SYSCON1	0	RW	32	System control register 1
0x8000.0140	SYSFLG1	0	RD	32	System status flags register 1

Table 34. EP7312 Internal Registers (Big Endian Mode)

All internal registers in the EP7312 are reset (cleared to zero) by a system reset (i.e., nPOR, nURESET, or nPWRFL signals becoming active), except for the SDRAM refresh period register (DPFPR), the Real Time Clock data register (RTC DR), and the match register (RTCMR), which are only reset by nPOR becoming active. This ensures that the SDRAM contents and system time are preserved through a user reset or power fail condition.

Note: The following Register Descriptions refer to Little Endian Mode Only

6.1.1 PADR — Port A Data Register

ADDRESS: 0x8000.0000

Values written to this 8-bit read / write register will be output on Port A pins if the corresponding data direction bits are set high (port output). Values read from this register reflect the external state of Port A, not necessarily the value written to it. All bits are cleared by a system reset.

6.1.2 PBDR — Port B Data Register

ADDRESS: 0x8000.0001

Values written to this 8-bit read / write register will be output on Port B pins if the corresponding data direction bits are set high (port output). Values read from this register reflect the external state of Port B, not necessarily the value written to it. All bits are cleared by a system reset.

6.1.3 PDDR — Port D Data Register

ADDRESS: 0x8000.0003

Values written to this 8-bit read / write register will be output on Port D pins if the corresponding data direction bits are set low (port output). Values read from this register reflect the external state of Port registers in the EP7312 are reset (cleared to zero) by a system reset (i.e., nPOR, nURESET, or nP-WRFL signals becoming active), except for the SDRAM refresh period register (SDRFPR), the Real Time Clock data register (RTCDR), and the match register (RTCMR), which are only reset by nPOR becoming active. This ensures that the SDRAM contents and system time are preserved through a user reset or power fail condition.

Note: The following Register Descriptions refer to Little Endian Mode Only

6.1.4 PADDR — Port A Data Direction Register

ADDRESS: 0x8000.0040

Bits set in this 8-bit read / write register will select the corresponding pin in Port A to become an output, clearing a bit sets the pin to input. All bits are cleared by a system reset.

6.1.5 PBDDR — Port B Data Direction Register

ADDRESS: 0x8000.0041

Bits set in this 8-bit read / write register will select the corresponding pin in Port B to become an output, clearing a bit sets the pin to input. All bits are cleared by a system reset.

6.1.6 PDDDR — Port D Data Direction Register

ADDRESS: 0x8000.0043

Bits cleared in this 8-bit read / write register will select the corresponding pin in Port D to become an output, setting a bit sets the pin to input. All bits are cleared by a system reset so that Port D is output by default.

6.1.7 PEDR — Port E Data Register

ADDRESS: 0x8000.0080

Values written to this 3-bit read / write register will be output on Port E pins if the corresponding data direction bits are set high (port output). Values read from this register reflect the external state of Port E, not necessarily the value written to it. All bits are cleared by a system reset.

6.1.8 PEDDR — Port E Data Direction Register

ADDRESS: 0x8000.00C0

Bits set in this 3-bit read / write register will select the corresponding pin in Port E to become an output, while the clearing bit sets the pin to input. All bits are cleared by a system reset so that Port E is input by default.

6.2 System Control Registers

6.2.1 SYSCON1 — System Control Register 1

ADDRESS: 0x8000.0100

23	22	21	20	19	18
Reserved	Reserved	Reserved	IRTXM	WAKEDIS	EXCKEN
17-16	15	14	13	12	11
ADCKSEL	SIREN	CDENRX	CDENTX	LCDEN	DBGEN

TC2S	TC2M	TC1S	TC1M	Keyboard scan	

The system control register is a 21-bit read / write register which controls all the general configuration of the EP7312, as well as modes etc. for peripheral devices. All bits in this register are cleared by a system reset. The bits in the system control register SYSCON1 are defined in Table 35.

Bit	Description																								
0-3	<p>Keyboard scan: This 4-bit field defines the state of the keyboard column drives. The following table defines these states.</p> <table border="1" style="margin-left: 40px;"> <thead> <tr> <th style="text-align: left;">Keyboard Scan</th> <th style="text-align: left;">Column</th> </tr> </thead> <tbody> <tr><td style="text-align: center;">0</td><td>All driven high</td></tr> <tr><td style="text-align: center;">1</td><td>All driven low</td></tr> <tr><td style="text-align: center;">2-7</td><td>All high impedance (tristate)</td></tr> <tr><td style="text-align: center;">8</td><td>Column 0 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">9</td><td>Column 1 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">10</td><td>Column 2 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">11</td><td>Column 3 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">12</td><td>Column 4 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">13</td><td>Column 5 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">14</td><td>Column 6 only driven high all others high impedance</td></tr> <tr><td style="text-align: center;">15</td><td>Column 7 only driven high all others high impedance</td></tr> </tbody> </table>	Keyboard Scan	Column	0	All driven high	1	All driven low	2-7	All high impedance (tristate)	8	Column 0 only driven high all others high impedance	9	Column 1 only driven high all others high impedance	10	Column 2 only driven high all others high impedance	11	Column 3 only driven high all others high impedance	12	Column 4 only driven high all others high impedance	13	Column 5 only driven high all others high impedance	14	Column 6 only driven high all others high impedance	15	Column 7 only driven high all others high impedance

1	All driven low																								
2-7	All high impedance (tristate)																								
8	Column 0 only driven high all others high impedance																								
9	Column 1 only driven high all others high impedance																								
10	Column 2 only driven high all others high impedance																								
11	Column 3 only driven high all others high impedance																								
12	Column 4 only driven high all others high impedance																								
13	Column 5 only driven high all others high impedance																								
14	Column 6 only driven high all others high impedance																								
15	Column 7 only driven high all others high impedance																								
4	TC1M: Timer counter 1 mode. Setting this bit sets TC1 to prescale mode, clearing it sets free running mode.																								
5	TC1S: Timer counter 1 clock source. Setting this bit sets the TC1 clock source to 512 kHz, clearing it sets the clock source to 2 kHz.																								
6	TC2M: Timer counter 2 mode. Setting this bit sets TC2 to prescale mode, clearing it sets free running mode.																								
7	TC2S: Timer counter 2 clock source. Setting this bit sets the TC2 clock source to 512 kHz, clearing it sets the clock source to 2 kHz.																								
8	UART1EN: Internal UART enable bit. Setting this bit enables the internal UART.																								

Table 35. SYSCON1

Bit	Description
9	BZTOG: Bit to drive (i.e., toggle) the buzzer output directly when software mode of operation is selected (i.e., bit BZMOD = 0). See the BZMOD and BUZFREQ (SYSCON1) bits for more details.
10	BZMOD: This bit selects the buzzer drive mode. When BZMOD = 0, the buzzer drive output pin is connected directly to the BZTOG bit. This is the software mode. When BZMOD = 1, the buzzer drive is in the hardware mode. Two hardware sources are available to drive the pin. They are the TC1 or a fixed internally generated clock source. The selection of which source is used to drive the pin is determined by the state of the BUZFREQ bit in the SYSCON2 register. If the TC1 is selected, then the buzzer output pin is connected to the TC1 under flow bit. The buzzer output pin changes every time the timer wraps around. The frequency depends on what was programmed into the timer. See the description of the BUZFREQ and BZTOG bits (SYSCON2) for more details.
11	DBGEN: Setting this bit will enable the debug mode. In this mode, all internal accesses are output as if they were reads or writes to the expansion memory addressed by nCS5. nCS5 will still be active in its standard address range. In addition, the internal interrupt request and fast interrupt request signals to the ARM720T processor are output on Port E, bits 1 and 2. Note that these bits must be programmed to be outputs before this functionality can be observed. The clock to the CPU is output on Port E, Bit 0 to delineate individual accesses. For example, in debug mode: <div style="text-align: center;"> nCS5 = nCS5 or internal I/O strobe PE0 = CLK PE1 = nIRQ PE2 = nFIQ </div>
12	LCDEN: LCD enable bit. Setting this bit enables the LCD controller.
13	CDENTX: CODEC interface enable TX bit. Setting this bit enables the CODEC interface for data transmission to an external CODEC device.
14	CDENRX: CODEC interface enable RX bit. Setting this bit enables the CODEC interface for data reception from an external CODEC device. NOTE: Both CDENRX and CDENTX need to be enabled / disabled in tandem, otherwise data may be lost.
15	SIREN: HP SIR protocol encoding enable bit. This bit will have no effect if the UART is not enabled.
16-17	ADCKSEL: Microwire / SPI peripheral clock speed select. This two-bit field selects the frequency of the ADC sample clock, which is twice the frequency of the synchronous serial ADC interface clock. The table below shows the available frequencies for operation when in PLL mode. These bits are also used to select the shift clock frequency for the SSI2 interface when set into master mode. The frequencies obtained in 13.0 MHz mode can be found in Table 1 on page 10 .

ADCKSEL	ADC Sample Frequency (kHz) — SMPCLK	ADC Clock Frequency (kHz) — ADCCLK
00	8	4
01	32	16
10	128	64
11	256	128

Table 35. SYSCON1 (cont.)

Bit	Description
18	EXCKEN: External expansion clock enable. If this bit is set, the EXPCLK is enabled continuously as a free running clock with the same frequency and phase as the CPU clock, assuming that the main oscillator is running. This bit should not be left set all the time for power consumption reasons. If the system enters the Standby State, the EXPCLK will become undefined. If this bit is clear, EXPCLK will be active during memory cycles to expansion slots that have external wait state generation enabled only.
19	WAKEDIS: Setting this bit disables waking up from the Standby State, via the wakeup input.
20	IRTXM: IrDA TX mode bit. This bit controls the IrDA encoding strategy. Clearing this bit means that each zero bit transmitted is represented as a pulse of width 3/16th of the bit rate period. Setting this bit means each zero bit is represented as a pulse of width 3/16th of the period of 115,200-bit rate clock (i.e., 1.6 μ s regardless of the selected bit rate). Setting this bit will use less power, but will probably reduce transmission distances.

Table 35. SYSCON1 (cont.)

6.2.2 SYSCON2— System Control Register 2

ADDRESS: 0x8000.1100

15	14	13	12	11-10	9	8
Reserved	BUZFREQ	CLKENSL	OSTB	Reserved	SS2MAEN	UART2EN

SS2RXEN	PC CARD2	PC CARD1	SS2TXEN	KBWEN	DRAMZ	KBD6
						0
						SERSEL

The SYSCON2 register is reset to all 0s on power up.

Bit	Description						
0	<p>SERSEL: The only affect of this bit is to select either SSI2 or the CODEC interface to the external pins. See the table below for the selection options.</p> <p>NOTE: If the DAISEL bit of SYSCON3 is set, then it overrides the state of the SERSEL bit, and thus the external pins are connected to the DAI interface.</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th style="text-align: center;">SERSEL Value</th> <th style="text-align: center;">Selected Serial Device to External Pins</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">0</td> <td style="text-align: center;">Master / slave SSI2</td> </tr> <tr> <td style="text-align: center;">1</td> <td style="text-align: center;">CODEC</td> </tr> </tbody> </table>	SERSEL Value	Selected Serial Device to External Pins	0	Master / slave SSI2	1	CODEC
SERSEL Value	Selected Serial Device to External Pins						
0	Master / slave SSI2						
1	CODEC						
1	<p>KBD6: The state of this bit determines how many of the Port A inputs are OR'ed together to create the keyboard interrupt. When zero (the reset state), all eight of the Port A inputs will generate a keyboard interrupt. When set high, only Port A bits 0 to 5 will generate an interrupt from the keyboard. It is assumed that the keyboard row lines are connected into Port A.</p>						
2	<p>DRAMZ: The bit determines the width of the DRAM memory interface, where: 0=32-bit DRAM and 1=16-bit DRAM.</p>						
3	<p>KBWEN: When the KBWEN bit is high, the EP7312 will awaken from a power saving state into the Operating State when a high signal is on one of Port A's inputs (irrespective of the state of the interrupt mask register). This is called the Keyboard Direct Wakeup mode. In this mode, the interrupt request does not have to get serviced. If the interrupt is masked (i.e., the interrupt mask register 2 (INTMR2) bit 0 is low), the processor simply starts re-executing code from where it left off before it entered the power saving state. If the interrupt is non-masked, then the processor will service the interrupt.</p>						
4	<p>SS2TXEN: Transmit enable for the synchronous serial interface 2. The transmit side of SSI2 will be disabled until this bit is set. When set low, this bit also disables the SSICLK pin (to save power) in master mode, if the receive side is low.</p>						
5	<p>PC CARD1: Enable for the interface to the CL-PS6700 device for PC Card slot 1. The main effect of this bit is to reassign the functionality of Port B, bit 0 to the PRDY input from the CL-PS6700 devices, and to ensure that any access to the nCS4 address space will be according to the CL-PS6700 interface protocol.</p>						
6	<p>PC CARD2: Enable for the interface to the CL-PS6700 device for PC Card slot 2. The main effect of this bit is to reassign the functionality of Port B, bit 1 to the PRDY input from the CL-PS6700 devices and to ensure that any access to the nCS5 address space will be according to the CL-PS6700 interface protocol.</p>						

Table 36. SYSCON2

Bit	Description
7	SS2RXEN: Receive enable for the synchronous serial interface 2. The receive side of SSI2 will be disabled until this bit is set. When both SSI2TXEN and SSI2RXEN are disabled, the SSI2 interface will be in a power saving state.
8	UART2EN: Internal UART2 enable bit. Setting this bit enables the internal UART2.
9	SS2MAEN: Master mode enable for the synchronous serial interface 2. When low, SSI2 will be configured for slave mode operation. When high, SSI2 will be configured for master mode operation. This bit also controls the directionality of the interface pins.
12	OSTB: This bit (operating system timing bit) is for use only with the 13 MHz clock source mode. Normally it will be set low, however when set high it will cause a 500 kHz clock to be generated for the timers instead of the 541 kHz which would normally be available. The divider to generate this frequency is not clocked when this bit is set low.
13	CLKENSL: CLKEN select. When low, the CLKEN signal will be output on the RUN/CLKEN pin. When high, the RUN signal will be output on RUN/CLKEN.
14	BUZFREQ: The BUZFREQ bit is used to select which hardware source will be used as the source to drive the buzzer output pin. When BUZFREQ = 0, the buzzer signal generated from the on-chip timer (TC1) is output. When BUZFREQ = 1, a fixed frequency clock is output (500 Hz when running from the PLL, 528 Hz in the 13 MHz external clock mode). See the BZMOD and the BZTOG bits (SYSCON2) for more details.

Table 36. SYSCON2 (cont.)

6.2.3 SYSCON3 — System Control Register 3

ADDRESS: 0x8000.2200

15	14	13	12	11	10	9	8
Reserved	Reserved	Reserved	Reserved	Reserved	ENPD67	128Fs	Reserved
7	6	5	4	3	2	1	0
VERSN[2] Reserved	VERSN[1] Reserved	VERSN[0] Reserved	ADCCKNSEN	DAISEL	CLKCTL1	CLKCTL0	ADCCON

This register is an extension of SYSCON1 and SYSCON2, containing additional control for the EP7312. The bits of this third system control register are defined in Table 37.

Bit	Description																				
0	ADCCON: Determines whether the ADC Configuration Extension field SYNCIO[16-31] is to be used for ADC configuration data. When this bit = 0 (default state) the ADC Configuration Byte SYNCIO[0-7] only is used for backwards compatibility. When this bit = 1, the ADC Configuration Extension field in the SYNCIO register is used for ADC Configuration data and the value in the ADC Configuration Byte (SYNCIO[0-6]) selects the length of the data (8-bit to 16-bit).																				
1:2	CLKCTL[0-1]: Determines the frequency of operation of the processor / memory bus and wait state scaling. The table below lists the available options.																				
	<table border="1"> <thead> <tr> <th>CLKCTL[1-0] Value</th> <th>Processor Frequency</th> <th>Memory Bus Frequency</th> <th>Wait State Scaling</th> </tr> </thead> <tbody> <tr> <td style="text-align: center;">00</td> <td style="text-align: center;">18.432 MHz</td> <td style="text-align: center;">18.432 MHz</td> <td style="text-align: center;">1</td> </tr> <tr> <td style="text-align: center;">01</td> <td style="text-align: center;">36.864 MHz</td> <td style="text-align: center;">36.864 MHz</td> <td style="text-align: center;">2</td> </tr> <tr> <td style="text-align: center;">10</td> <td style="text-align: center;">49.152 MHz</td> <td style="text-align: center;">36.864 MHz</td> <td style="text-align: center;">2</td> </tr> <tr> <td style="text-align: center;">11</td> <td style="text-align: center;">73.728 MHz</td> <td style="text-align: center;">36.864 MHz</td> <td style="text-align: center;">2</td> </tr> </tbody> </table>	CLKCTL[1-0] Value	Processor Frequency	Memory Bus Frequency	Wait State Scaling	00	18.432 MHz	18.432 MHz	1	01	36.864 MHz	36.864 MHz	2	10	49.152 MHz	36.864 MHz	2	11	73.728 MHz	36.864 MHz	2
CLKCTL[1-0] Value	Processor Frequency	Memory Bus Frequency	Wait State Scaling																		
00	18.432 MHz	18.432 MHz	1																		
01	36.864 MHz	36.864 MHz	2																		
10	49.152 MHz	36.864 MHz	2																		
11	73.728 MHz	36.864 MHz	2																		
	NOTE: To determine the number of wait states programmed refer to Table 44 on page 88 and Table 45 on page 89. When operating at 13 MHz, the CLKCTL[0-1] bits should not be changed from the default value of '00'. Under no circumstances should the CLKCTL bits be changed using a buffered write.																				
3	DAISEL: When set, selects DAI interface. This action defaults to SSI (DAISEL bit is low).																				
4	ADCCKNSEN: When set, configuration data is transmitted on ADCOUT at the rising edge of the ADCCLK, and data is read back on the falling edge on the ADCIN pin. When clear (default), the opposite edges are used.																				
5-7	VERSN[0-2]: Additional read-only version bits — will read '000'																				
8	Reserved. This bit must be set to zero																				
9	128Fs: When set, this bit selects the 128 fs mode. 0 by default.																				
10	ENPD67: Pd[6-7] control the byte mask of the SDRAM interface. Setting of this bit allows their use as GPIO bits as in previous devices for applications not using SDRAM.																				

Table 37. SYSCON3

6.2.4 SYSFLG1 — System Status Flags Register

ADDRESS: 0x8000.0140

31-30	29	28	27	26
VERID	ID	BOOTBIT1	BOOTBIT0	SSIBUSY
23	22	21-16	23	22
UTXFF1	URXFE1	RTCDIV	UTXFF1	URXFE1
15	14	13	12	11
CLDFLG	PFFLG	RSTFLG	NBFLG	UBUSY1
7-4	3	2	1	0
DID	WUON	WUDR	DCDET	MCDR

The system status flags register is a 32-bit read only register, which indicates various system information. The bits in the system status flags register SYSFLG1 are defined in Table 38.

Bit	Description
0	MCDR: Media changed direct read. This bit reflects the INVERTED non-latched status of the media changed input.
1	DCDET: This bit will be set if a non-battery operated power supply is powering the system (it is the inverted state of the nEXTPWR input pin).
2	WUDR: Wake up direct read. This bit reflects the non-latched state of the wakeup signal.
3	WUON: This bit will be set if the system has been brought out of the Standby State by a rising edge on the wakeup signal. It is cleared by a system reset or by writing to the HALT or STDBY locations.
4-7	DID: Display ID nibble. This 4-bit nibble reflects the latched state of the four LCD data lines. The state of the four LCD data lines is latched by the LCDEN bit, and so it will always reflect the last state of these lines before the LCD controller was enabled.
8	CTS: This bit reflects the current status of the clear to send (CTS) modem control input to UART1.
9	DSR: This bit reflects the current status of the data set ready (DSR) modem control input to UART1.
10	DCD: This bit reflects the current status of the data carrier detect (DCD) modem control input to UART1.
11	UBUSY1: UART1 transmitter busy. This bit is set while UART1 is busy transmitting data, it is guaranteed to remain set until the complete byte has been sent, including all stop bits.
12	NBFLG: New battery flag. This bit will be set if a low to high transition has occurred on the nBATCHG input, it is cleared by writing to the STFCLR location.
13	RSTFLG: Reset flag. This bit will be set if the RESET button has been pressed, forcing the nURESET input low. It is cleared by writing to the STFCLR location.
14	PFFLG: Power Fail Flag. This bit will be set if the system has been reset by the nPWRFL input pin, it is cleared by writing to the STFCLR location.
15	CLDFLG: Cold start flag. This bit will be set if the EP7312 has been reset with a power on reset, it is cleared by writing to the STFCLR location.

Table 38. SYSFLG1

Bit	Description															
16-21	RTCDIV: This 6-bit field reflects the number of 64 Hz ticks that have passed since the last increment of the RTC. It is the output of the divide by 64 chain that divides the 64 Hz tick clock down to 1 Hz for the RTC. The MSB is the 32 Hz output, the LSB is the 1 Hz output.															
22	URXFE1: UART1 receiver FIFO empty. The meaning of this bit depends on the state of the UFI-FOEN bit in the UART1 bit rate and line control register. If the FIFO is disabled, this bit will be set when the RX holding register is empty. If the FIFO is enabled, the URXFE bit will be set when the RX FIFO is empty.															
23	UTXFF1: UART1 transmit FIFO full. The meaning of this bit depends on the state of the UFI-FOEN bit in the UART1 bit rate and line control register. If the FIFO is disabled, this bit will be set when the TX holding register is full. If the FIFO is enabled, the UTXFF bit will be set when the TX FIFO is full.															
24	CRXFE: CODEC RX FIFO empty bit. This will be set if the 16-byte CODEC RX FIFO is empty.															
25	CTXFF: CODEC TX FIFO full bit. This will be set if the 16-byte CODEC TX FIFO is full.															
26	SSIBUSY: Synchronous serial interface busy bit. This bit will be set while data is being shifted in or out of the synchronous serial interface, when clear data is valid to read.															
27-28	BOOTBIT[0-1]: These bits indicate the default (power-on reset) bus width of the ROM interface. See <i>Memory Configuration Registers</i> for more details on the ROM interface bus width. The state of these bits reflect the state of Port E[0-1] during power on reset, as shown in the table below.															
<table border="1"> <thead> <tr> <th>PE[1] (BOOTBIT1)</th> <th>PE[0] (BOOTBIT0)</th> <th>Boot Option</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>32-bit</td> </tr> <tr> <td>0</td> <td>1</td> <td>8-bit</td> </tr> <tr> <td>1</td> <td>0</td> <td>16-bit</td> </tr> <tr> <td>1</td> <td>1</td> <td>Reserved</td> </tr> </tbody> </table>		PE[1] (BOOTBIT1)	PE[0] (BOOTBIT0)	Boot Option	0	0	32-bit	0	1	8-bit	1	0	16-bit	1	1	Reserved
PE[1] (BOOTBIT1)	PE[0] (BOOTBIT0)	Boot Option														
0	0	32-bit														
0	1	8-bit														
1	0	16-bit														
1	1	Reserved														
29	ID: Will always read “1” for the EP7312 device															
30-31	VERID: Version ID bits. These 2 bits determine the version ID for the EP7312. Will read “01” for the initial version.															

Table 38. SYSFLG1 (cont.)

6.2.5 SYSFLG2 — System Status Register 2

ADDRESS: 0x8000.1140

23	22	21-12	11	10-7	6
UTXFF2	URXFE2	Reserved	UBUSY2	Reserved	CKMODE
5	4	3	2	1	0
SS2TXUF	SS2TXFF	SS2RXFE	RESFRM	RESVAL	SS2RXOF

The bits of the second system status register are defined in Table 39.

Bit	Description
0	SS2RXOF: Master / slave SSI2 RX FIFO overflow. This bit is set when a write is attempted to a full RX FIFO (i.e., when RX is still receiving data and the FIFO is full). This can be cleared in one of two ways: 1. Empty the FIFO (remove data from FIFO) and then write to SRXEOF location. 2. Disable the RX (affects of disabling the RX will not take place until a full SSI2 clock cycle after it is disabled)
1	RESVAL: Master / slave SSI2 RX FIFO residual byte present, cleared by popping the residual byte into the SSI2 RX FIFO or by a new RX frame sync pulse.
2	RESFRM: Master / slave SSI2 RX FIFO residual byte present, cleared only by a new RX frame sync pulse.
3	SS2RXFE: Master / slave SSI2 RX FIFO empty bit. This will be set if the 16 x 16 RX FIFO is empty.
4	SS2TXFF: Master / slave SSI2 TX FIFO full bit. This will be set if the 16 x 16 TX FIFO is full. This will get cleared when data is removed from the FIFO or the EP7312 is reset.
5	SS2TXUF: Master / slave SSI2 TX FIFO Underflow bit. This will be set if there is attempt to transmit when TX FIFO is empty. This will be cleared when FIFO gets loaded with data.
6	CKMODE: This bit reflects the status of the CLKSEL (PE[2]) input, latched during nPOR. When low, the PLL is running and the chip is operating in 18.432–73.728 MHz mode. When high the chip is operating from an external 13 MHz clock.
11	UBUSY2: UART2 transmitter busy. This bit is set while UART2 is busy transmitting data; it is guaranteed to remain set until the complete byte has been sent, including all stop bits.
22	URXFE2: UART2 receiver FIFO empty. The meaning of this bit depends on the state of the UFI-FOEN bit in the UART2 bit rate and line control register. If the FIFO is disabled, this bit will be set when the RX holding register contains is empty. If the FIFO is enabled, the URXFE bit will be set when the RX FIFO is empty.
23	UTXFF2: UART2 transmit FIFO full. The meaning of this bit depends on the state of the UFI-FOEN bit in the UART2 bit rate and line control register. If the FIFO is disabled, this bit will be set when the TX holding register is full. If the FIFO is enabled, the UTXFF bit will be set when the TX FIFO is full.

Table 39. SYSFLG2

6.3 Interrupt Registers

6.3.1 INTSR1 — Interrupt Status Register 1

ADDRESS: 0x8000.0240

15	14	13	12	11	10	9	8
SSEOTI	UMSINT	URXINT1	UTXINT1	TINT	RTCMI	TC2OI	TC1OI
7	6	5	4	3	2	1	0
EINT3	EINT2	EINT1	CSINT	MCINT	WEINT	BLINT	EXTFIQ

The interrupt status register is a 32-bit read only register. The interrupt status register reflects the current state of the first 16 interrupt sources within the EP7312. Each bit is set if the appropriate interrupt is active. The interrupt assignment is given in Table 40.

Bit	Description
0	EXTFIQ: External fast interrupt. This interrupt will be active if the nEXTFIQ input pin is forced low and is mapped to the FIQ input on the ARM720T processor.
1	BLINT: Battery low interrupt. This interrupt will be active if no external supply is present (nEXTPWR is high) and the battery OK input pin BATOK is forced low. This interrupt is de-glitched with a 16 kHz clock, so it will only generate an interrupt if it is active for longer than 125 μ sec. It is mapped to the FIQ input on the ARM720T processor and is cleared by writing to the BLEOI location. NOTE: BLINT is disabled during the Standby State.
2	WEINT: Tick Watch dog expired interrupt. This interrupt will become active on a rising edge of the periodic 64 Hz tick interrupt clock if the tick interrupt is still active (i.e., if a tick interrupt has not been serviced for a complete tick period). It is mapped to the FIQ input on the ARM720T processor and the TEOI location. NOTE: WEINT is disabled during the Standby State. Watch dog timer tick rate is 64 Hz (in 13 MHz and 73.728–18.432 MHz modes). Watchdog timer is turned off during the Standby State.
3	MCINT: Media changed interrupt. This interrupt will be active after a rising edge on the nMEDCHG input pin has been detected, This input is de-glitched with a 16 kHz clock so it will only generate an interrupt if it is active for longer than 125 μ sec. It is mapped to the FIQ input on the ARM7TDMI processor and is cleared by writing to the MCEOI location. On power-up, the Media change pin (nMEDCHG) is used as an input to force the processor to either boot from the internal Boot ROM, or from external memory. After power-up, the pin can be used as a general purpose FIQ interrupt pin.
4	CSINT: CODEC sound interrupt, generated when the data FIFO has reached half full or empty (depending on the interface direction). It is cleared by writing to the COEOI location.
5	EINT1: External interrupt input 1. This interrupt will be active if the nEINT1 input is active (low). It is cleared by returning nEINT1 to the passive (high) state.
6	EINT2: External interrupt input 2. This interrupt will be active if the nEINT2 input is active (low). It is cleared by returning nEINT2 to the passive (high) state.
7	EINT3: External interrupt input 3. This interrupt will be active if the EINT3 input is active (high). It is cleared by returning EINT3 to the passive (low) state.
8	TC1OI: TC1 under flow interrupt. This interrupt becomes active on the next falling edge of the timer counter 1 clock after the timer counter has under flowed (reached zero). It is cleared by writing to the TC1EOI location.

Table 40. INTSR1

Bit	Description
9	TC2OI: TC2 under flow interrupt. This interrupt becomes active on the next falling edge of the timer counter 2 clock after the timer counter has under flowed (reached zero). It is cleared by writing to the TC2EOI location.
10	RTCMI: RTC compare match interrupt. This interrupt becomes active on the next rising edge of the 1 Hz Real Time Clock (one second later) after the 32-bit time written to the Real Time Clock match register exactly matches the current time in the RTC. It is cleared by writing to the RTCEOI location.
11	TINT: 64 Hz tick interrupt. This interrupt becomes active on every rising edge of the internal 64 Hz clock signal. This 64 Hz clock is derived from the 15-stage ripple counter that divides the 32.768 kHz oscillator input down to 1 Hz for the Real Time Clock. This interrupt is cleared by writing to the TEOI location. NOTE: TINT is disabled / turned off during the Standby State.
12	UTXINT1: Internal UART1 transmit FIFO half-empty interrupt. The function of this interrupt source depends on whether the UART1 FIFO is enabled. If the FIFO is disabled (FIFOEN bit is clear in the UART1 bit rate and line control register), this interrupt will be active when there is no data in the UART1 TX data holding register and be cleared by writing to the UART1 data register. If the FIFO is enabled this interrupt will be active when the UART1 TX FIFO is half or more empty, and is cleared by filling the FIFO to at least half full.
13	URXINT1: Internal UART1 receive FIFO half full interrupt. The function of this interrupt source depends on whether the UART1 FIFO is enabled. If the FIFO is disabled this interrupt will be active when there is valid RX data in the UART1 RX data holding register and be cleared by reading this data. If the FIFO is enabled this interrupt will be active when the UART1 RX FIFO is half or more full or if the FIFO is non empty and no more characters have been received for a three character time out period. It is cleared by reading all the data from the RX FIFO.
14	UMSINT: Internal UART1 modem status changed interrupt. This interrupt will be active if either of the two modem status lines (CTS or DSR) change state. It is cleared by writing to the UMSEOI location.
15	SSEOTI: Synchronous serial interface end of transfer interrupt. This interrupt will be active after a complete data transfer to and from the external ADC has been completed. It is cleared by reading the ADC data from the SYNCIO register.

Table 40. INTSR1 (cont.)

6.3.2 INTMR1 — Interrupt Mask Register 1

ADDRESS: 0x8000.0280

15	14	13	12	11	10	9	8
SSEOTI	UMSINT	URXINT	UTXINT	TINT	RTCMI	TC2OI	TC1OI
7	6	5	4	3	2	1	0
EINT3	EINT2	EINT1	CSINT	MCINT	WEINT	BLINT	EXTFIQ

This interrupt mask register is a 32-bit read / write register, which is used to selectively enable any of the first 16 interrupt sources within the EP7312. The four shaded interrupts all generate a fast interrupt request to the ARM720T processor (FIQ), this will cause a jump to processor virtual address 0000.001C. All other interrupts will generate a standard interrupt request (IRQ), this will cause a jump to processor virtual address 0000.0018. Setting the appropriate bit in this register enables the corresponding interrupt. All bits are cleared by a system reset. Please refer to *INTSR1 Interrupt Status Register 1* for individual bit details.

6.3.3 INTSR2 — Interrupt Status Register 2

ADDRESS: 0x8000.1240

15-14	13	12	11-3	2	1	0
Reserved	URXINT2	UTXINT2	Reserved	SS2TX	SS2RX	KBDINT

The interrupt status register also reflects the current state of the new interrupt sources within the EP7312. Each bit is set if the appropriate interrupt is active. The interrupt assignment is given in Table 41.

Bit	Description
0	KBDINT: Keyboard interrupt. This interrupt is generated whenever a key is pressed, from the logical OR of the first 6 or all 8 of the Port A inputs (depending on the state of the KBD6 bit in the SYSCON2 register. The interrupt request is latched and can be de-asserted by writing to the KBDEOI location. NOTE: KBDINT is not deglitched.
1	SS2RX: Synchronous serial interface 2 receives FIFO half or greater full interrupt. This is generated when RX FIFO contains 8 or more half-words. This interrupt is cleared only when the RX FIFO is emptied or one SSI2 clock after RX is disabled.
2	SS2TX: Synchronous serial interface 2 transmit FIFO less than half empty interrupt. This is generated when TX FIFO contains fewer than 8 byte pairs. This interrupt gets cleared by loading the FIFO with more data or disabling the TX. One synchronization clock required when disabling the TX side before it takes effect.
12	UTXINT2: UART2 transmit FIFO half empty interrupt. The function of this interrupt source depends on whether the UART2 FIFO is enabled. If the FIFO is disabled (FIFOEN bit is clear in the UART2 bit rate and line control register), this interrupt will be active when there is no data in the UART2 TX data holding register and be cleared by writing to the UART2 data register. If the FIFO is enabled, this interrupt will be active when the UART2 TX FIFO is half or more empty and is cleared by filling the FIFO to at least half full.
13	URXINT2: UART2 receive FIFO half full interrupt. The function of this interrupt source depends on whether the UART2 FIFO is enabled. If the FIFO is disabled, this interrupt will be active when there is valid RX data in the UART2 RX data holding register and be cleared by reading this data. If the FIFO is enabled, this interrupt will be active when the UART2 RX FIFO is half or more full or if the FIFO is non-empty, and no more characters have been received for a three-character time-out period, it is cleared by reading all the data from the RX FIFO.

Table 41. INSTR2

6.3.4 INTMR2 — Interrupt Mask Register 2

ADDRESS: 0x8000.1280

15-14	13	12	11-3	2	1	0
Reserved	URXINT2	UTXINT2	Reserved	SS2TX	SS2RX	KBDINT

Please refer to INTSR2 for individual bit details.

6.3.5 INTSR3 — Interrupt Status Register 3

ADDRESS: 0x8000.2240

7-1	0
Reserved	DAIINT

Each bit is set if the appropriate interrupt is active. The interrupt assignment is given in Table 42 on page 86.

Bit	Description
0	DAIINT: DAI interface interrupt. The cause must be determined by reading the DAI status register. It is mapped to the FIQ interrupt on the ARM720T processor

Table 42. INTSR3

6.3.6 INTMR3 — Interrupt Mask Register 3

ADDRESS: 0x8000.2280

7-1	0
Reserved	DAIINT

This register is an extension of INTMR1 and INTMR2, containing interrupt mask bits for the EP7312. Please refer to INTSR3 for individual bit details.

6.4 Memory Configuration Registers

6.4.1 MEMCFG1 — Memory Configuration Register 1

ADDRESS: 0x8000.0180

31-24	23-16	15-8	7-0
nCS[3] configuration	nCS[2] configuration	nCS[1] configuration	nCS[0] configuration

Expansion and ROM space is selected by one of eight chip selects. One of the chip selects (nCS[6]) is used internally for the on-chip SRAM, and the configuration is hardwired for 32-bit-wide, minimum-wait-state operation. nCS[7] is used for the on-chip Boot ROM and the configuration field is hardwired for 8-bit-wide, minimum-wait-state operation. Data written to the configuration fields for either nCS[6] or nCS[7] will be ignored. Two of the chip selects (nCS[4-5]) can be used to access two CL-PS6700 PC CARD controller devices, and when either of these interfaces is enabled, the configuration field for the appropriate chip select in the MEMCFG2 register is ignored. When the PC CARD1 or 2 control bit in the SYSCON2 register is disabled, then nCS[4] and nCS[5] are active as normal and can be programmed using the relevant fields of MEMCFG2, as for the other four chip selects. All of the six external chip selects are active for 256 Mbytes and the timing and bus transfer width can be programmed individually. This is accomplished by programming the six-byte-wide fields contained in two 32-bit registers, MEMCFG1 and MEMCFG2. All bits in these registers are cleared by a system reset (except for the nCS[6] and nCS[7] configurations).

The Memory Configuration Register 1 is a 32-bit read / write register which sets the configuration of the four expansion and ROM selects nCS[0-3]. Each select is configured with a 1-byte field starting with expansion select 0.

6.4.2 MEMCFG2 — Memory Configuration Register 2

ADDRESS: 0x8000.01C0

31-24	23-16	15-8	7-0
(Boot ROM)	(Local SRAM)	nCS[5] configuration	nCS[4] configuration
7	6	5-2	1-0
CLKENB	SQAEN	Wait States Field	Bus width

The Memory Configuration Register 2 is a 32-bit read / write register which sets the configuration of the two expansion and ROM selects nCS[4-5]. Each select is configured with a 1-byte field starting with expansion select 4.

Each of the six non-reserved byte fields for chip select configuration in the memory configuration registers are identical and define the number of wait states, the bus width, enable EXPCLK output during accesses and enable sequential mode access. This byte field is defined below. This arrangement applies to nCS[0-3], and nCS[4-5] when the PC CARD enable bits in the SYSCON2 register are not set. The state of these bits is ignored for the Boot ROM and local SRAM fields in the MEMCFG2 register.

Table 43 on page 88 defines the bus width field. Note that the effect of this field is dependent on the two BOOTBIT bits that can be read in the SYSFLG1 register. All bits in the memory configuration register are cleared by a system reset, and the state of the BOOTBIT bits are determined by Port E bits 0 and 1 on the EP7312 during power-on reset. The state of PE[1] and PE[0] determine whether the EP7312 is going to boot from either 32-bit-wide, 16-bit-wide or 8-bit-wide ROMs.

Table 44 on page 88 shows the values for the wait states for random and sequential wait states at 13 and 18 MHz bus rates. At 36 MHz bus rate, the encoding becomes more complex. Table 45 on page 89 preserves compatibility with the previous devices, while allowing the previously unused bit combinations to specify more variations of random and sequential wait states.

Bus Width Field	BOOTBIT1	BOOTBIT0	Expansion Transfer Mode	Port E bits 1,0 during NPOR reset
00	0	0	32-bit wide bus access	Low, Low
01	0	0	16-bit wide bus access	Low, Low
10	0	0	8-bit wide bus access	Low, Low
11	0	0	Reserved	Low, Low
00	0	1	8-bit wide bus access	Low, High
01	0	1	Reserved	Low, High
10	0	1	32-bit wide bus access	Low, High
11	0	1	16-bit wide bus access	Low, High
00	1	0	16-bit wide bus access	High, Low
01	1	0	32-bit wide bus access	High, Low
10	1	0	Reserved	High, Low
11	1	0	8-bit wide bus access	High, Low

Table 43. Values of the Bus Width Field

Value	No. of Wait States Random	No. of Wait States Sequential
00	4	3
01	3	2
10	2	1
11	1	0

Table 44. Values of the Wait State Field at 13 MHz and 18 MHz

Bit 3	Bit 2	Bit 1	Bit 0	Wait States Random	Wait States Sequential
0	0	0	0	8	3
0	0	0	1	7	3
0	0	1	0	6	3
0	0	1	1	5	3
0	1	0	0	4	2
0	1	0	1	3	2

1	1	0	0	4	0
1	1	0	1	3	0
1	1	1	0	2	0
1	1	1	1	1	0

Table 45. Values of the Wait State Field at 36 MHz

Bit	Description
6	SQAEN: Sequential access enable. Setting this bit will enable sequential accesses that are on a quad word boundary to take advantage of faster access times from devices that support page mode. The sequential access will be faulted after four words (to allow video refresh cycles to occur), even if the access is part of a longer sequential access. In addition, when this bit is not set, non-sequential accesses will have a single idle cycle inserted at least every four cycles so that the chip select is de-asserted periodically between accesses for easier debug.
7	CLKENB: Expansion clock enable. Setting this bit enables the EXPCLK to be active during accesses to the selected expansion device. This will provide a timing reference for devices that need to extend bus cycles using the EXPRDY input. Back-to-back (but not necessarily page mode) accesses will result in a continuous clock. This bit will only affect EXPCLK when the PLL is being used (i.e., in 73.728–18.432 MHz mode). When operating in 13 MHz mode, the EXPCLK pin is an input, so it is not affected by this register bit. To save power internally, it should always be set to zero when operating in 13 MHz mode.

Table 46. MEMCFG2

See the “AC Electrical Specification” section in the *EP7312 Data Sheet* for more details on bus timing.

The memory area decoded by CS[6] is reserved for the on-chip SRAM, hence this does not require a configuration field in MEMCFG2. It is automatically set up for 32-bit-wide, no-wait-state accesses. For the Boot ROM, it is automatically set up for 8-bit, no wait state accesses.

Chip selects nCS[4] and nCS[5] are used to select two CL-PS6700 PC CARD controller devices. These have a multiplexed 16-bit wide address / data interface, and the configuration bytes in the MEMCFG2 register have no meaning when these interfaces are enabled.

6.5 Timer / Counter Registers

6.5.1 TC1D — Timer Counter 1 Data Register

ADDRESS: 0x8000.0300

The timer counter 1 data register is a 16-bit read / write register which sets and reads data to TC1. Any value written will be decremented on the next rising edge of the clock.

6.5.2 TC2D — Timer Counter 2 Data Register

ADDRESS: 0x8000.0340

The timer counter 2 data register is a 16-bit read / write register which sets and reads data to TC2. Any value written will be decremented on the next rising edge of the clock.

6.5.3 RTCDR — Real Time Clock Data Register

ADDRESS: 0x8000.0380

The Real Time Clock data register is a 32-bit read / write register, which sets and reads the binary time in the RTC. Any value written will be incremented on the next rising edge of the 1 Hz clock. This register is reset only by nPOR.

6.5.4 RTCMR — Real Time Clock Match Register

ADDRESS: 0x8000.03C0

The Real Time Clock match register is a 32-bit read / write register, which sets and reads the binary match time to RTC. Any value written will be compared to the current binary time in the RTC, if they match it will assert the RTCMI interrupt source. This register is reset only by nPOR.

6.6 LEDFLSH Register

ADDRESS: 0x8000.22C0

6	5-2	1-0
Enable	Duty ratio	Flash rate

The output is enabled whenever LEDFLSH[6] = 1. When enabled, PDDDR[0] needs to be configured as an output pin and the bit cleared to ‘0’ (See “PDDDR — Port D Data Direction Register”.) When the LED Flasher is disabled, the pin defaults to being used as Port D bit 0. Thus, this will ensure that the LED will be off when disabled.

The flash rate is determined by the LEDFLSH[0-1] bits, in the following way:

LEDFLSH[0-1]	Flash Period (sec)
00	1
01	2
10	3
11	4

Table 47. LED Flash Rates

LEDFLSH[2-5]	Duty Ratio (time on: time off)	LEDFLSH[2-5]	Duty Ratio (time on: time off)
0000	01:15	1000	09:07
0001	02:14	1001	10:06
0010	03:13	1010	11:05
0011	04:12	1011	12:04
0100	05:11	1100	13:03
0101	06:10	1101	14:02
0110	07:09	1110	15:01
0111	08:08	1111	16:00 (continually on)

Table 48. LED Duty Ratio

6.7 SDCONF — SDRAM Control Register

ADDRESS: 0x8000.2300

31-11	10	9	8-7	6-5	4-2	1-0
Reserved	SDACTIVE	CLKCTL	SDWIDTH	SDSIZE	Reserved	CASLAT

Bit	Description
0-1	How many clock cycles after CAS before the device is ready for reading or writing. '00' => Reserved, '01' => Reserved, '10' => CAS Latency = 2, '11' => CAS Latency = 3. The default value is '10' for CAS latency = 2.
2-4	Reserved
5-6	The capacity of each SDRAM. The values are: '00'=>16Mits, '01'=>64Mbits, '10'=>128Mbits, '11'=>256Mbits
7-8	The width of each SDRAM. '00'=>4bits, '01'=>8bits, '10'=>16 bits, '11'=>32 bits

Bit	Description
9	Control over the SDRAM clock. '0'=> SDRAM clock is permanently enabled except when in standby mode. '1'=>SDRAM clock stops when the EP7312 is put into inactive mode i.e., SDACTIVE = '0', or when EP7312 is in standby mode.
10	Enables the SDRAM controller: '0' disables, '1' enables. The SDRAM controller will only initialize if SDACTIVE is set to 1. After initialization, resetting this parameter will cause the SDRAM controller to enter an inactive state. It will remain in this state until SDACTIVE is set to 1.
11-31	Reserved

6.8 SDRFPR — SDRAM Refresh Period Register

ADDRESS: 0x8000.2340

31-16	15-0
Reserved	REFRATE

This 16-bit R/W register sets the interval between SDRAM refresh commands. The value programmed is the interval in BLCK cycles e.g. for a 16µs refresh period with a BCLK of 36MHz, the following value should be programmed:

$$16 \times 10^{-6} * 36 \times 10^6 = 576$$

The refresh timer is set to 256 by nPOR to ensure a refresh time of better than 16µs even at 13 MHz. This register should not be programmed to a value below 2 otherwise the internal bus may become locked.

This register replaces DPFPR, which is no longer active. Writes to this register are ignored. Reads from this register will produce unpredictable results.

6.9 UNIQID Register

0x8000.2440

31-0

This 32-bit register is set at the factory and is used to implement the MaverickKey™ functionality and to create 32-bit unique SDMI-assigned IDs. The unique number is read-only and cannot be modified by software.

6.10 RANDID0 Register

8000.2700

31-0

This 32-bit register is set at the factory and is used to implement the MaverickKey™ functionality and to create 128-bit unique random IDs. The unique number is read-only and cannot be modified by software.

6.11 RANDID1 Register

8000.2704

63-32

This 32-bit register is set at the factory and is used to implement the MaverickKey™ functionality and to create 128-bit unique random IDs. The unique number is read-only and cannot be modified by software.

6.12 RANDID2 Register

8000.2708

95-64

This 32-bit register is set at the factory and is used to implement the MaverickKey™ functionality and to create 128-bit unique random IDs. The unique number is read-only and cannot be modified by software.

6.13 RANDID3 Register

8000.2708C

127-96

This 32-bit register is set at the factory and is used to implement the MaverickKey™ functionality and to create 128-bit unique random IDs. The unique number is read-only and cannot be modified by software.

6.14 PMPCON — Pump Control Register

ADDRESS: 0x8000.0400

11-8	7-4	3-0
Drive 1 pump ratio	Drive 0 from AC source ratio	Drive 0 from battery ratio

The Pulse Width Modulator (PWM) pump control register is a 16-bit read / write register which sets and controls the variable mark space ratio drives for the two PWMs. All bits in this register are cleared by a system reset. (The top four bits are unused. They should be written as zeroes, and will read as undefined).

Bit	Description
0-3	Drive 0 from battery: This 4-bit field controls the “on” time for the Drive 0 PWM pump while the system is powered from batteries. Setting these bits to 0 disables this pump, while setting these bits to 1 allows the pump to be driven in a 1:16 duty ratio, 2 in a 2:16 duty ratio etc. up to a 15:16 duty ratio. An 8:16 duty ratio results in a square wave of 96 kHz when operating with an 18.432 MHz master clock, or 101.6 kHz when operating from the 13 MHz source.
4-7	Drive 0 from AC: This 4-bit field controls the “on” time for the Drive 0 DC to DC pump, while the system is powered from a non-battery type power source. Setting these bits to 0 disables this pump, setting these bits to 1 allows the pump to be driven in a 1:16 duty ratio, 2 in a 2:16 duty ratio, etc. up to a 15:16 duty ratio. An 8:16 duty ratio results in a square wave of 96 kHz when operating with an 18.432 MHz master clock, or 101.6 kHz when operating from the 13 MHz source. NOTE: The EP7312 monitors the power supply input pins (i.e., BATOK and NEXTPWR) to determine which of the above fields to use.
8-11	Drive 1 pump ratio: This 4-bit field controls the “on” time for the drive1 PWM pump. Setting these bits to 0 disables this pump, while setting these bits to 1 allows the pump to be driven in a 1:16 duty ratio, 2 in a 2:16 duty ratio, etc. up to a 15:16 duty ratio. An 8:16 duty ratio results in a square wave of 96 kHz when operating with an 18.432 MHz master clock, or 101.6 kHz when operating from the 13 MHz source.

Table 49. PMPCON

The state of the output drive pins is latched during power on reset, this latched value is used to determine the polarity of the drive output. The sense of the PWM control lines is summarized in Table 50.

Initial State of Drive 0 or Drive 1 During Power on Reset	Sense of Drive 0 or Drive 1	Polarity of Bias Voltage
Low	Active high	+ve
High	Active low	-ve

Table 50. Sense of PWM control lines

External input pins that would normally be connected to the output from comparators monitoring the PWM output are also used to enable these clocks. These are the FB[0-1] pins. When FB[0] is high, the PWM is disabled. The same applies to FB[1]. They are read upon power-up.

Note: To maximize power savings, the drive ratio fields should be used to disable the PWMs, instead of the FB pins. The clocks that source the PWMs are disabled when the drive ratio fields are zeroed.

6.15 CODR — CODEC Interface Data Register

ADDRESS: 0x8000.0440

The CODR register is an 8-bit read / write register, to be used with the CODEC interface. This is selected by the appropriate setting of bit 0 (SERSEL) of the SYSCON2 register. Data written to or read from this register is pushed or popped onto the appropriate 16-byte FIFO buffer. Data from this buffer is then serialized and sent to or received from the CODEC sound device. When the CODEC is enabled, the CODEC interrupt CSINT is generated repetitively at 1/8th of the byte transfer rate and the state of the FIFOs can be read in the system flags register. The net data transfer rate to / from the CODEC device is 8 kbytes/s, giving an interrupt rate of 1 kHz.

6.16 UART Registers

6.16.1 UARTDR1-2, UART1-2 Data Registers

ADDRESS: 0x8000.0480 and 0x8000.1480

10	9	8	7-0
OVERR	PARERR	FRMERR	RX data

The UARTDR registers are 11-bit read and 8-bit write registers for all data transfers to or from the internal UARTs 1 and 2.

Data written to these registers is pushed onto the 16-byte data TX holding FIFO if the FIFO is enabled. If not it is stored in a one byte holding register. This write will initiate transmission from the UART.

The UART data read registers are made up of the 8-bit data byte received from the UART together with three bits of error status. If the FIFO is enabled, data read from this register is popped from the 16 byte data RX FIFO. If the FIFO is not enabled, it is read from a one byte buffer register containing the last byte received by the UART. If it is enabled, data received and error status is automatically pushed onto the RX FIFO. The RX FIFO is 10-bits wide by 16 deep.

Note: These registers should be accessed as words.

Bit	Description
8	FRMERR: UART framing error. This bit is set if the UART detected a framing error while receiving the associated data byte. Framing errors are caused by non-matching word lengths or bit rates.
9	PARERR: UART parity error. This bit is set if the UART detected a parity error while receiving the data byte.
10	OVERR: UART over-run error. This bit is set if more data is received by the UART and the FIFO is full. The overrun error bit is not associated with any single character and so is not stored in the FIFO. If this bit is set, the entire contents of the FIFO is invalid and should be cleared. This error bit is cleared by reading the UARTDR register.

Table 51. UARTDR1-2 UART1-2

6.16.2 UBRLCR1–2 UART1–2 Bit Rate and Line Control Registers

ADDRESS: 0x8000.04C0 and 0x8000.14C0

18-17	16	15	14	13	12	11-0
WRDLEN	FIFOEN	XSTOP	EVENPRT	PRTEN	BREAK	Bit rate divisor

The bit rate divisor and line control register is a 19-bit read / write register. Writing to these registers sets the bit rate and mode of operation for the internal UARTs.

Bit	Description																				
0-11	<p>BRATED: Bit rate divisor. This 12-bit field sets the bit rate. If the system is operating from the PLL clock, then the bit rate divider is fed by a clock frequency of 3.6864 MHz, which is then further divided internally by 16 to give the bit rate. The formula to give the divisor value for any bit rate when operating from the PLL clock is: $\text{Divisor} = (230400/\text{bit rate divisor} + 1)$. A value of zero in this field is illegal when running from the PLL clock. The tables below show some example bit rates with the corresponding divisor value. In 13 MHz mode, the clock frequency fed to the UART is 1.8571 MHz. In this mode, zero is a legal divisor value, and will generate the maximum possible bit rate. The tables below show the bit rates available for both 18.432 MHz and 13 MHz operation.”</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th style="text-align: center;">Divisor Value</th> <th style="text-align: center;">Bit Rate Running From the PLL Clock</th> </tr> </thead> <tbody> <tr><td style="text-align: center;">0</td><td style="text-align: center;">—</td></tr> <tr><td style="text-align: center;">1</td><td style="text-align: center;">115200</td></tr> <tr><td style="text-align: center;">2</td><td style="text-align: center;">76800</td></tr> <tr><td style="text-align: center;">3</td><td style="text-align: center;">57600</td></tr> <tr><td style="text-align: center;">5</td><td style="text-align: center;">38400</td></tr> <tr><td style="text-align: center;">11</td><td style="text-align: center;">19200</td></tr> <tr><td style="text-align: center;">15</td><td style="text-align: center;">14400</td></tr> <tr><td style="text-align: center;">23</td><td style="text-align: center;">9600</td></tr> <tr><td style="text-align: center;">95</td><td style="text-align: center;">2400</td></tr> </tbody> </table>	Divisor Value	Bit Rate Running From the PLL Clock	0	—	1	115200	2	76800	3	57600	5	38400	11	19200	15	14400	23	9600	95	2400

6.17 LCD Registers

6.17.1 LCDCON — LCD Control Register

ADDRESS: 0x8000.02C0

31	30	29-25	24-19	18-13	12-0
GSMD2	GSMD1	AC prescale	Pixel prescale	Line length	Video buffer size

The LCD control register is a 32-bit read / write register that controls the size of the LCD screen and the operating mode of the LCD controller. Refer to the system description of the LCD controller for more information on video buffer mapping.

The LCDCON register should only be reprogrammed when the LCD controller is disabled.

Bit	Description
0-12	<p>Video buffer size: The video buffer size field is a 13-bit field that sets the total number of bits x 128 (quad words) in the video display buffer. This is calculated from the formula:</p> $\text{Video buffer size} = (\text{Total bits in video buffer} / 128) - 1$ <p>i.e., for a 640 x 240 LCD and 4 bits-per-pixel, the size of the video buffer is equal to 614400 bits.</p> $\text{Video buffer} = 640 \times 240 \times 4 = 614400 \text{ bits}$ <p>Video buffer size field = $(614400 / 128) - 1 = 4799$ or 0x12BF hex. The minimum value allowed is 3 for this bit field.</p>
13-18	<p>Line length: The line length field is a 6-bit field that sets the number of pixels in one complete line. This field is calculated from the formula:</p> $\text{line length} = (\text{Number of pixels in line} / 16) - 1$ <p>i.e., for 640 x 240 LCD Line length = $(640 / 16) - 1 = 39$ or 0x27 hex. The minimum value that can be programmed into this register is a 1 (i.e., 0 is not a legal value).</p>

Table 53. LCDCON

Bit	Description
19-24	<p>Pixel prescale: The pixel prescale field is a 6-bit field that sets the pixel rate prescale. The pixel rate is always derived from a 36.864 MHz clock when in PLL mode, and is calculated from the formula: $\text{Pixel rate (MHz)} = 36.864 / (\text{Pixel prescale} + 1)$ When the EP7312 is operating at 13 MHz, pixel rate is given by the formula: $\text{Pixel rate (MHz)} = 13 / (\text{Pixel prescale} + 1)$ The pixel prescale value can be expressed in terms of the LCD size by the formula: When the EP7312 is operating @ 18.432 MHz: $\text{Pixel prescale} = (36864000 / (\text{Refresh Rate} \times \text{Total pixels in display})) - 1$ When the EP7312 is operating @ 13 MHz: $\text{Pixel prescale} = (13000000 / (\text{Refresh Rate} \times \text{Total pixels in display})) - 1$ Refresh Rate is the screen refresh frequency (70 Hz to avoid flicker) The value should be rounded down to the nearest whole number and zero is illegal and will result in no pixel clock. EXAMPLE: For a system being operated in the 18.432–73.728 MHz mode, with a 640 x 240 screen size, and 70 Hz screen refresh rate desired, the LCD Pixel prescale equals $36.864E6 / (70 \times 640 \times 240) - 1 = 2.428$ Rounding 2.428 down to the nearest whole number equals 2. This gives an actual pixel rate of $36.864E6 / (2+1) = 12.288 \text{ MHz}$, which gives an actual refresh frequency of $12.288E6 / (640 \times 240) = 80 \text{ Hz}$. NOTE: As the CL[2] low pulse time is doubled after every CL[1] high pulse this refresh frequency is only an approximation, the accurate formula is $12.288E6 / ((640 \times 240) + 120) = 79.937 \text{ Hz}$.</p>
25-29	<p>AC prescale: The AC prescale field is a 5-bit number that sets the LCD AC bias frequency. This frequency is the required AC bias frequency for a given manufacturer's LCD plate. This frequency is derived from the frequency of the line clock (CL[1]). The LCD M signal will toggle after n+1 counts of the line clock (CL[1]) where n is the number programmed into the AC prescale field. This number must be chosen to match the manufacturer's recommendation. This is normally 13, but must not be exactly divisible by the number of lines in the display.</p>
30	<p>GSMD1: Grayscale mode bit number 1. Setting this bit enables 2 or 4 bits-per-pixel (01 or 11, respectively) grayscale. (Also see the GSMD2 bit definition.) Clearing this bit enables 1 bpp (00) grayscale only.</p> <p>NOTE: Grayscale is always enabled when using the EP7312 LCD Controller. Direct mapping of the frame buffer bits to the LCD display is not supported. However, this can be accomplished by simply programming the palette register contents to correspond with the frame buffer bit value (i.e., for 1 bpp (00) Direct mapping program the PALLSW register nibble [0-3] with zeros, and nibble [4-7] with ones.)</p>
31	<p>GSMD2: Grayscale mode bit number 2. Setting this bit enables 4 bpp (11) grayscale (15 gray-scales.) Clearing this bit enables 2 bits-per-pixel (01) grayscale.</p>

Table 53. LCDCON (cont.)

6.17.2 *PALLSW* — *Least Significant Word* — *LCD Palette Register*

ADDRESS: 0x8000.0580

31-28	27-24	23-20	19-16	15-12	11-8	7-4	3-0
Grayscale value for pixel value 7	Grayscale value for pixel value 6	Grayscale value for pixel value 5	Grayscale value for pixel value 4	Grayscale value for pixel value 3	Grayscale value for pixel value 2	Grayscale value for pixel value 1	Grayscale value for pixel value 0

The least and most significant word LCD palette registers make up a 64-bit read / write register which maps the logical pixel value to a physical grayscale level. The 64-bit register is made up of 16 x 4-bit nibbles, each nibble defines the grayscale level associated with the appropriate pixel value. If the LCD controller is operating in two bits-per-pixel, only the lower 4 nibbles are valid (D[0-15] in the least significant word). Similarly, one bit-per-pixel means only the lower 2 nibbles are valid (D[0-7]) in the least significant word.

6.17.3 *PALMSW* — *Most Significant Word* — *LCD Palette Register*

ADDRESS: 0x8000.0540

31-28	27-24	23-20	19-16	15-12	11-8	7-4	3-0
Grayscale value for pixel value 15	Grayscale value for pixel value 14	Grayscale value for pixel value 13	Grayscale value for pixel value 12	Grayscale value for pixel value 11	Grayscale value for pixel value 10	Grayscale value for pixel value 9	Grayscale value for pixel value 8

The pixel to grayscale level assignments and the actual physical color and pixel duty ratio for the grayscale values are shown in Table 54 on page 100. Note that colors 8–15 are the inverse of colors 7–0 respectively. This means that colors 7 and 8 are identical. Therefore, in reality only 15 grayscales available, not 16. The steps in the grayscale are non-linear, but have been chosen to give a close approximation to perceived linear grayscales. This is due to the eye being more sensitive to changes in gray level close to 50% gray (See *PALLSW* description).

Grayscale Value	Duty Cycle	% Pixels Lit	% Step Change
0	0	0%	11.1%
1	1/9	11.1%	8.9%
2	1/5	20.0%	6.7%
3	4/15	26.7%	6.6%
4	3/9	33.3%	6.7%
5	2/5	40.0%	5.4%
6	4/9	44.4%	5.6%
7	1/2	50.0%	0.0%
8	1/2	50.0%	5.6%
9	5/9	55.6%	5.4%
10	3/5	60.0%	6.7%
11	6/9	66.7%	6.6%
12	11/15	73.3%	6.7%
13	4/5	80.0%	8.9%
14	8/9	88.9%	11.1%
15	1	100%	

Table 54. Grayscale Value to Color Mapping

6.17.4 FBADDR — LCD Frame Buffer Start Address Register

ADDRESS: 0x8000.1000

This register contains the start address for the LCD Frame Buffer. It is assumed that the frame buffer starts at location 0x000.0000 within each chip select memory region. Therefore, the value stored within the FBADDR register is only the value of the chip select where the frame buffer is located. On reset, this will be set to 0xC. The register is 4 bits wide (bits [0-3]). This register must only be reprogrammed when the LCD is disabled (i.e., setting the LCDEN bit within SYSCON2 low).

6.18 SSI Registers

6.18.1 SYNCIO — Synchronous Serial ADC Interface Data Register

ADDRESS: 0x8000.0500

In the default mode, the bits in SYNCIO have the following meaning:

31-15	14	13	12-8	7-0
Reserved	TXFRMEN	SMCKEN	Frame length	ADC Configuration Byte

In extended mode, the following applies:

15	14	13	12-7	6-0
Reserved	TXFRMEN	SMCKEN	Frame length	ADC Configuration Length

ADC Configuration Extension

NOTE: The frame length in extended mode is 6 bits wide to allow up to 16 write bits, 1 null bit and 16 read bits (= 33 cycles).

SYNCIO is a 32-bit read / write register. The data written to the SYNCIO register configures the master only SSI. In default mode, the least significant byte is serialized and transmitted out of the synchronous serial interface¹ (i.e., SSI1) to configure an external ADC, MSB first. In extended mode, a variable number of bits are sent from SYNCIO[16-31] as determined by the ADC Configuration Length. The transfer clock will automatically be started at the programmed frequency and a synchronization pulse will be issued. The ADCIN pin is sampled on every positive going clock edge (or the falling clock edge, if ADCCKNSEN in SYSCON3 is set) and the result is shifted in to the SYNCIO read register.

During data transfer, the SSIBUSY bit is set high; at the end of a transfer the SSEOTI interrupt will be asserted. To clear the interrupt the SYNCIO register must be read. The data read from the SYNCIO register is the last sixteen bits shifted out of the ADC.

The length of the data frame can be programmed by writing to the SYNCIO register. This allows many different ADCs to be accommodated. The device is SPI- / Microwire-compatible (transfers are in multiples of 8 bits). However, to be compatible with some non-SPI / Microwire devices, the data written to the ADC device can be anything between 8 to 16 bits. This is user-definable per the ADC Configuration Extension section of the SYNCIO register.

Bit	Description
0-7 or 0-6	ADC Configuration Byte: When the ADCCON control bit in the SYSCON3 register = 0, this is the 8-bit configuration data to be sent to the ADC. When the ADCCON control bit in the SYSCON3 register = 1, this field determines the length of the ADC configuration data held in the ADC Configuration Extension field for sending to the ADC.
8-12 or 7-12	Frame length: The Frame Length field is the total number of shift clocks required to complete a data transfer. In default mode, MAX148/9 (and for many ADCs), this is 25 = (8 for configuration byte + 1 null bit + 16 bits result). In extended mode, AD7811/12, this is 23 = (10 for configuration byte + 3 null + 10 bits result).
13	SMCKEN: Setting this bit will enable a free running sample clock at twice the programmed ADC clock frequency to be output on the SMPLCK pin.
14	TXFRMEN: Setting this bit will cause an ADC data transfer to be initiated. The value in the ADC configuration field will be shifted out to the ADC and depending on the frame length programmed, a number of bits will be captured from the ADC. If the SYNCIO register is written to with the TXFRMEN bit low, no ADC transfer will take place, but the Frame length and SMCKEN bits will be affected.
16-31	ADC Configuration Extension: When the ADCCON control bit in the SYSCON3 register = 0. When the ADCCON control bit in the SYSCON3 register = 1, this field is the configuration data to be sent to the ADC. The ADC Configuration Extension field length is determined by the value held in the ADC Configuration Length field (SYNCIO[0-6]).

Table 55. SYNCIO

6.19 STFCLR — Clear All “Start Up Reason” Flags Location

ADDRESS: 0x8000.05C0

A write to this location will clear all the “Start Up Reason” flags in the system flags status register SYS-FLG. The “Start Up Reason” flags should first read to determine the reason why the chip was started (i.e., a new battery was installed). Any value may be written to this location.

6.20 End Of Interrupt Locations

The “End of Interrupt” locations that follow are written to after the appropriate interrupt has been serviced. The write is performed to clear the interrupt status bit, so that other interrupts can be serviced. Any value may be written to these locations.

6.20.1 BLEOI Battery Low End of Interrupt

ADDRESS: 0x8000.0600

A write to this location will clear the interrupt generated by a low battery (falling edge of BATOK with nEXTPWR high).

6.20.2 MCEOI Media Changed End of Interrupt

ADDRESS: 0x8000.0640

A write to this location will clear the interrupt generated by a falling edge of the nMEDCHG input pin.

6.20.3 TEOI Tick End of Interrupt Location

ADDRESS: 0x8000.0680

A write to this location will clear the current pending tick interrupt and tick watch dog interrupt.

6.20.4 TC1EOI TC1 End of Interrupt Location

ADDRESS: 0x8000.06C0

A write to this location will clear the under flow interrupt generated by TC1.

6.20.5 TC2EOI TC2 End of Interrupt Location

ADDRESS: 0x8000.0700

A write to this location will clear the under flow interrupt generated by TC2.

6.20.6 RTCEOI — RTC Match End of Interrupt

ADDRESS: 0x8000.0740

A write to this location will clear the RTC match interrupt

6.20.7 UMSEOI — UART1 Modem Status Changed End of Interrupt

ADDRESS: 0x8000.0780

A write to this location will clear the modem status changed interrupt.

6.20.8 COEOI — CODEC End of Interrupt Location

ADDRESS: 0x8000.07C0

A write to this location clears the sound interrupt (CSINT).

6.20.9 KBDEOI — Keyboard End of Interrupt Location

ADDRESS: 0x8000.1700

A write to this location clears the KBDINT keyboard interrupt.

6.20.10 SRXEOF — End of Interrupt Location

ADDRESS: 0x8000.1600

A write to this location clears the SSI2 RX FIFO overflow status bit.

6.21 State Control Registers

6.21.1 STDBY — Enter the Standby State Location

ADDRESS: 0x8000.0840

A write to this location will put the system into the Standby State by halting the main oscillator. A write to this location while there is an active interrupt will have no effect.

- Notes:
- 1) Before entering the Standby State, the LCD Controller should be disabled. The LCD controller should be enabled on exit from the Standby State.
 - 2) If the EP7312 is attempting to get into the Standby State when there is a pending interrupt request, it will not enter into the low power mode. The instruction will get executed, but the processor will ignore the command.

6.21.2 HALT — Enter the Idle State Location

ADDRESS: 0x8000.0800

A write to this location will put the system into the Idle State by halting the clock to the processor until an interrupt is generated. A write to this location while there is an active interrupt will have no effect.

6.22 SS2 Registers

6.22.1 SS2DR — Synchronous Serial Interface 2 Data Register

ADDRESS: 0x8000.1500

This is the 16-bit-wide data register for the full-duplex master / slave SSI2 synchronous serial interface. Writing data to this register will initiate a transfer. Writes need to be word writes and the bottom 16 bits are transferred to the TX FIFO. Reads will be 32 bits as well with the lower 16 bits containing RX data, and the upper 16-bits should be ignored. Although the interface is byte-oriented, data is written in two bytes at a time to allow higher bandwidth transfer. It is up to the software to assemble the bytes for the data stream in an appropriate manner.

All reads / writes to this register must be word reads / writes.

6.22.2 SS2POP — Synchronous Serial Interface 2 Pop Residual Byte

ADDRESS: 0x8000.16C0

This is a write-only location which will cause the contents of the RX shift register to be popped into the RX FIFO, thus enabling a residual byte to be read. The data value written to this register is ignored. This location should be used in conjunction with the RESVAL and RESFRM bits in the SYSFLG2 register.

6.23 DAI Register Definitions

There are five registers within the DAI Interface, one control register, three data registers, and one status register. The control register is used to mask or unmask interrupt requests to service the DAI's FIFOs, and to select whether an on-chip or off-chip clock is used to drive the bit rate, and to enable / disable operation. The first pair of data register addresses the top of the Right Channel Transmit FIFO and the bottom of the Right Channel Receive FIFO. A read accesses the receive FIFOs, and a write the transmit FIFOs. Note that these are four physically separate FIFOs to allow full-duplex transmission. The status register contains bits which signal FIFO overrun and underrun errors and transmit and receive FIFO service requests. Each of these status conditions signal an interrupt request to the interrupt controller. The status register also flags when the transmit FIFOs are not full when the receive FIFOs are not empty.

6.23.1 DAIR — DAI Control Register

ADDRESS: 0x8000.2000

31-24	23	22	21	20	19	18	17	16	15-0
Reserved	Reserved	RCRM	RCTM	LCRM	LCTM	Reserved	ECS	DAIEN	Reserved

The DAI control register (DAIR) contains eight different bit fields that control various functions within the DAI interface.

Bit	Description
0-15	Reserved Must be set to 0x0404
7	Reserved
15	Reserved
16	<p>DAIEN: DAI Interface Enable</p> <p>0 — DAI operation disabled, control of the SDIN, SDOOUT, SCLKLRCK, and LRCK pins given to the SSI2 / CODEC / DAI pin multiplexing logic to assign I/O pins 60-64 to another block.</p> <p>1 — DAI operation enabled</p> <p>Note that by default, the SSI / CODEC have precedence over the DAI interface in regard to the use of the I/O pins. Nevertheless, when bit 3 (DAISEL) of register SYSCON3 is set to 1, then the above mentioned DAI ports are connected to I/O pins 60–64.</p>
17	ECS: External Clock Select selects external MCLK when = 1.
18	Reserved Must be 0.
19	<p>LCTM: Left Channel Transmit FIFO Interrupt Mask</p> <p>0 — Left Channel Transmit FIFO half-full or less condition does not generate an interrupt (LCTS bit ignored).</p> <p>1 — Left Channel Transmit FIFO half-full or less condition generates an interrupt (state of LCTS sent to interrupt controller).</p>
20	<p>LCRM: Left Channel Receive FIFO Interrupt Mask</p> <p>0 — Left Channel Receive FIFO half-full or more condition does not generate an interrupt (LCRS bit ignored).</p> <p>1 — Left Channel Receive FIFO half-full or more condition generates an interrupt (state of LCRS sent to interrupt controller).</p>
21	<p>RCTM: Right Channel Transmit FIFO Interrupt Mask</p> <p>0 — Right Channel Transmit FIFO half-full or less condition does not generate an interrupt (RCTS bit ignored).</p> <p>1 — Right Channel Transmit FIFO half-full or less condition generates an interrupt (state of RCTS sent to interrupt controller).</p>
22	<p>RCRM: Right Channel Receive FIFO Interrupt Mask</p> <p>0 — Right Channel Receive FIFO half-full or more condition does not generate an interrupt (RCRS bit ignored).</p> <p>1 — Right Channel Receive FIFO half-full or more condition generates an interrupt (state of RCRS sent to interrupt controller).</p>
23	Reserved
24-31	Reserved

Table 56. DAI Control Register

6.23.1.1 *DAI Enable (DAIEN)*

The DAI enable (DAIEN) bit is used to enable and disable all DAI operation.

When the DAI is disabled, all of its clocks are powered down to minimize power consumption. Note that DAIEN is the only control bit within the DAI interface that is reset to a known state. It is cleared to zero to ensure the DAI timing is disabled following a reset of the device.

When the DAI timing is enabled, SCLK begins to transition and the start of the first frame is signaled by driving the LRCK pin low. The rising and falling-edge of LRCK coincides with the rising and falling-edge of SCLK. As long as the DAIEN bit is set, the DAI interface operates continuously, transmitting and receiving 128 bit data frames. When the DAIEN bit is cleared, the DAI interface is disabled immediately, causing the current frame which is being transmitted to be terminated. Clearing DAIEN resets the DAI's interface FIFOs. However DAI data register 3, the control register and the status register are not reset. Therefore, the user must ensure these registers are properly reconfigured before re-enabling the DAI interface.

6.23.1.2 *DAI Interrupt Generation*

The DAI interface can generate four maskable interrupts and four non-maskable interrupts, as described in the sections below. Only one interrupt line is wired into the interrupt controller for the whole DAI interface. This interrupt is the wired OR of all eight interrupts (after masking where appropriate). The software servicing the interrupts must read the status register in the DAI to determine which source(s) caused the interrupt. It is possible to prevent any DAI sources causing an interrupt by masking the DAI interrupt in the interrupt controller register.

6.23.1.3 *Left Channel Transmit FIFO Interrupt Mask (LCTM)*

The Left channel sample transmit FIFO interrupt mask (LCTM) bit is used to mask or enable the left channel sample transmit FIFO service request interrupt. When LATM = 0, the interrupt is masked and the state of the Left Channel Transmit FIFO service request (LCTS) bit within the DAI status register is ignored by the interrupt controller. When LCTM = 1, the interrupt is enabled and whenever LCTS is set (one) an interrupt request is made to the interrupt controller. Note that programming LCTM = 0 does not affect the current state of LCTS or the Left Channel Transmit FIFO logic's ability to set and clear LCTS; it only blocks the generation of the interrupt request.

6.23.1.4 *Left Channel Receive FIFO Interrupt Mask (LARM)*

The left channel sample receive FIFO interrupt mask (LCRM) bit is used to mask or enable the Left Channel Receive FIFO service request interrupt. When LCRM = 0, the interrupt is masked and the state of the left channel sample receive FIFO service request (LCRS) bit within the DAI status register is ignored by the interrupt controller. When LCRM = 1, the interrupt is enabled and whenever LCRS is set (one) an interrupt request is made to the interrupt controller. Note that programming LCRM = 0 does not affect the current state of LCRS or the Left Channel Receive FIFO logic's ability to set and clear LCRS, it only blocks the generation of the interrupt request.

6.23.1.5 *Right Channel Transmit FIFO Interrupt Mask (RCTM)*

The Right Channel Transmit FIFO interrupt mask (RCTM) bit is used to mask or enable the right channel transmit FIFO service request interrupt. When RCTM = 0, the interrupt is masked and the state of the Right Channel Transmit FIFO service request (RCTS) bit within the DAI status register is ignored by the interrupt controller. When RCTM = 1, the interrupt is enabled and whenever RCTS is set (one) an interrupt request is made to the interrupt controller. Note that programming RCTM = 0 does not affect the current state of RCTS or the Right Channel Transmit FIFO logic's ability to set and clear RCTS, for it only blocks the generation of the interrupt request.

6.23.1.6 *Right Channel Receive FIFO Interrupt Mask (RCRM)*

The Right Channel Receive FIFO interrupt mask (RCRM) bit is used to mask or enable the Right Channel Receive FIFO service request interrupt. When RCRM = 0, the interrupt is masked and the state of the Right Channel Receive FIFO service request (RCRS) bit within the DAI status register is ignored by the interrupt controller. When RCRM = 1, the interrupt is enabled, and whenever RCRS is set (one), an interrupt request is made to the interrupt controller. Note that programming RCRM = 0 does not affect the current state of RCRS or the Right Channel Receive FIFO logic's ability to set and clear RCRS, for it only blocks the generation of the interrupt request.

6.23.2 DAI64Fs Control Register

ADDRESS: 0x8000.2600

The DAI now includes a divider network for the frequency of the clock source. The EP7312 provides for both 128 and 64 times the sample frequency (128 fs and 64 fs) to better support the various MP3 sample rates. There are two clocks to choose from: 73.728 MHz PLL clock as well as the 11.2896 Mhz external clock. The purpose is support more devices that use the 64 fs rate. Both clocks are fixed rate clocks so the divider network (AUDIV) is required.

31-15	14-8	7-6	5	4	3	2	1	0
	AUDDIV		LOOPBACK		MCLK256EN	AUDCLKSRC	AUDIOCLKEN	I2SFS64

Bit	Description
0	I2SFS64: 0 => 128 fs 1=>64 fs If high, SYSCON3 bit 9 must be low. The converse must also be observed.
1	AUDCLKEN: Enable audio clock generator
2	AUDCLKSRC: Clock Source 0=> 73.728 MHz (PLL) 1=> 11.2896 MHz (External Clock)
3	MCLK256EN: Selects MCLK (256 fs) or the BUZZ pin
4	Reserved
5	LOOPBACK: Test mode. Loops digital data internally. Data normally going to DAC loops back internally.
6-7	Reserved
8-14	AUDIV: Frequency divisor for sample frequency and bit clock using either the external clock or the PLL clock for the audio clock generator
15-31	Reserved

Table 57. DAI64Fs Control Register

Clock Source (MHz)	Sample Frequency (KHz)	128 fs Audio Bit Clock (MHz)	64 fs Audio Bit Clock (MHz)	128 fs Divisor (AUDDIV)	64 fs Divisor (AUDDIV)
73.728	8	1.0240	0.5120	36	72
11.2896	11.025	1.4112	0.7056	8	16
73.728	16	1.5360	0.7680	18	36

Table 58. Clock Source for 64 fs and 128 fs

6.23.3 DAI Data Registers

The DAI contains three data registers: DAIDR0 addresses the top entry of the Right Channel Transmit FIFO and bottom entry of the Right Channel Receive FIFO; DAIDR1 addresses the top and bottom entry of the Left Channel Transmit and Receive FIFOs, respectively; and DAIDR2 is used to perform enable and disable the DAI FIFOs.

6.23.3.1 DAIDR0 — DAI Data Register 0

ADDRESS: 0x8000.2040

31-16	15-0
Reserved	Bottom of Right Channel Receive FIFO
Read Access	
31-16	15-0
Reserved	Top of Right Channel Transmit FIFO
Write Access	

When DAI Data Register 0 (DAIDR0) is read, the bottom entry of the Right Channel Receive FIFO is accessed. As data is removed by the DAI's receive logic from the incoming data frame, it is placed into the top entry of the Right Channel Receive FIFO and is transferred down an entry at a time until it reaches the last empty location within the FIFO. Data is removed by reading DAIDR0, which accesses the bottom entry of the right channel FIFO. After DAIDR0 is read, the bottom entry is invalidated, and all remaining values within the FIFO automatically transfer down one location.

When DAIDR0 is written, the top-most entry of the Right Channel Transmit FIFO is accessed. After a write, data is automatically transferred down to the lowest location within the transmit FIFO which does not already contain valid data. Data is removed from the bottom of the FIFO one value at a time by the transmit logic, loaded into the correct position within the 64-bit transmit serial shifter, then serially shifted out onto the SDOOUT pin.

Table 59 shows DAIDR0. Note that the Transmit and Receive Right Channel FIFOs are cleared when the device is reset, or by writing a zero to DAIEN (DAI disabled). Also, note that writes to reserved bits are ignored and reads return zeros.

Bit	Description
0-15	RIGHT CHANNEL DATA: Transmit / Receive Right Channel FIFO Data Read — Bottom of Right Channel Receive FIFO data Write — Top of Right Channel Transmit FIFO data
16-31	Reserved

Table 59. DAI Data Register 0

6.23.3.2 DAIDR1 — DAI Data Register 1

ADDRESS: 0x8000.2080

31-16	15-0
Reserved	Bottom of Left Channel Receive FIFO
Read Access	
31-16	15-0
Reserved	Top of Left Channel Transmit FIFO
Write Access	

When DAI Data Register 1 (DAIDR1) is read, the bottom entry of the Left Channel Receive FIFO is accessed. As data is removed by the DAI's receive logic from the incoming data frame, it is placed into the top entry of the Left Channel Receive FIFO and is transferred down an entry at a time until it reaches the last empty location within the FIFO. Data is removed by reading DAIDR1, which accesses the bottom entry of the left channel FIFO. After DAIDR1 is read, the bottom entry is invalidated, and all remaining values within the FIFO automatically transfer down one location.

When DAIDR1 is written, the top-most entry of the Left Channel Transmit FIFO is accessed. After a write, data is automatically transferred down to the lowest location within the transmit FIFO which does not already contain valid data. Data is removed from the bottom of the FIFO one value at a time by the transmit logic. It is then loaded into the correct position within the 64-bit transmit serial shifter then serially shifted out onto the SDOOUT pin.

Table 60 shows DAIDR1. Note that the Transmit and Receive Left Channel FIFOs are cleared when the device is reset, or by writing a zero to DAIEN (DAI disabled). Also, note that writes to reserved bits are ignored and reads return zeros.

Bit	Description
0-15	LEFT CHANNEL DATA: Transmit / Receive Left Channel FIFO Data Read — Bottom of Left Channel Receive FIFO data Write — Top of Left Channel Transmit FIFO data
16-31	Reserved

Table 60. DAI Data Register 1

6.23.3.3 DAIDR2 — DAI Data Register 2

ADDRESS: 0x8000.20C0

31-21	20-16	15	14-0
Reserved	FIFO Channel Select	FIFOEN	Reserved

DAIDR2 is a 32-bit register that utilizes 21 bits and is used to enable and disable the FIFOs for the left and right channels of the DAI data stream. The left channel FIFO is enabled by writing 0x000D.8000 and disabled by writing 0x000D.0000. The right channel FIFO is enabled by writing 0x0011.8000 and disabled by writing 0x0011.0000. After writing a value to this register, wait until the FIFO operation complete bit (FIFO) is set in the DAI status register before writing another value to this register.

Bit	Description
0-14	Reserved
15	FIFOEN: FIFO Transmit Bit 0 — Disable Transmit 1 — Enable Transmit
16-20	FIFO CHANNEL SELECT: 01101b — Left channel select 10001b — Right channel select
21-31	Reserved

Table 61. DAI Data Register 2

6.23.4 DAISR — DAI Status Register

ADDRESS: 0x8000.2100

The DAI Status Register (DAISR) contains bits which signal FIFO overrun and underrun errors and FIFO service requests. Each of these conditions signal an interrupt request to the interrupt controller. The status register also flags when transmit FIFOs are not full, when the receive FIFOs are not empty, when a FIFO operation is complete, and when the right channel or left channel portion of the CODEC is enabled (no interrupt generated).

Bits which cause an interrupt signal the interrupt request as long as the bit is set. Once the bit is cleared, the interrupt is cleared. Read / write bits are called status bits, read-only bits are called flags. Status bits are referred to as “sticky” (once set by hardware, they must be cleared by software). Writing a one to a sticky status bit clears it, while writing a zero has no effect. Read-only flags are set and cleared by hardware, and writes have no effect. Additionally, some bits which cause interrupts have corresponding mask bits in the control register and are indicated in the section headings below. Note that the user has the ability to mask all DAI interrupts by clearing the DAI bit within the interrupt controller mask register INTMR3.

31-13	12	11	10	9	8	7
Reserved	FIFO	LCNE	LCNF	RCNE	RCNF	RCCELRO
6	5	4	3	2	1	0
RCNFLCTU	LCRORCRO	LCTURCTU	LCRS	LCTS	LCRSRCRS	LCTSRCTS

Bit	Description
0	<p>RCTS: Right Channel Transmit FIFO Service Request Flag (read-only)</p> <p>0 — Right Channel Transmit FIFO is more than half full (five or more entries filled) or DAI disabled</p> <p>1 — Right Channel Transmit FIFO is half full or less (four or fewer entries filled) and DAI operation is enabled, interrupt request signaled if not masked (if RCTM = 1)</p>
1	<p>RCRS: Right Channel Receive FIFO Service Request (read-only)</p> <p>0 — Right Channel Receive FIFO is less than half full (five or fewer entries filled) or DAI disabled</p> <p>1 — Right Channel Receive FIFO is half full or more (six or more entries filled) and DAI operation is enabled, interrupt request signaled if not masked (if RCRM = 1)</p>
2	<p>LCTS: Left Channel Transmit FIFO Service Request Flag (read-only)</p> <p>0 — Left Channel Transmit FIFO is more than half full or less (four or fewer entries filled) or DAI disabled.</p> <p>1 — Left Channel Transmit FIFO is half full or less (four or fewer entries filled) and DAI operation is enabled, interrupt request signaled if not masked (if LCTM = 1)</p>
3	<p>LCRS: 0 — Left Channel Receive FIFO is less than half full (five or fewer entries filled) or DAI disabled.</p> <p>1 — Left Channel Receive FIFO is half full or more (six or more entries filled) and DAI operation is enabled, interrupt request signalled if not masked (if LCRM = 1)</p>

Table 62. DAI Control, Data and Status Register Locations

Bit	Description
4	Right Channel Transmit FIFO Underrun 0 — Right Channel Transmit FIFO has not experienced an underrun 1 — Right Channel Transmit logic attempted to fetch data from transmit FIFO while it was empty, request interrupt
5	RCRO: Right Channel Receive FIFO Overrun 0 — Right Channel Receive FIFO has not experienced an overrun 1 — Right Channel Receive logic attempted to place data into receive FIFO while it was full, request interrupt
6	LCTU: Left Channel Transmit FIFO Underrun 0 — Left Channel Transmit FIFO has not experienced an underrun 1 — Left Channel Transmit logic attempted to fetch data from transmit FIFO while it was empty, request interrupt
7	LCRO: Left Channel Receive FIFO Overrun 0 — Left Channel Receive FIFO has not experienced an overrun 1 — Left Channel Receive logic attempted to place data into receive FIFO while it was full, request interrupt
8	RCNF: Right Channel Transmit FIFO Not Full (read-only) 0 — Right Channel Transmit FIFO is full 1 — Right Channel Transmit FIFO is not full
9	RCNE: Right Channel Receive FIFO Not Empty (read-only) 0 — Right Channel Receive FIFO is empty 1 — Right Channel Receive FIFO is not empty
10	LCNF: LCNETelecom Transmit FIFO Not Full (read-only) 0 — Left Channel Transmit FIFO is full 1 — Left Channel Transmit FIFO is not full
11	LCNE: Left Channel Receive FIFO Not Empty (read-only) 0 — Left Channel Receive FIFO is empty 1 — Left Channel Receive FIFO is not empty
12	FIFO: FIFO Operation Completed (read-only) 0 — A FIFO Operation has not completed since the last time this bit was cleared 1 — The FIFO Operation was completed
13	Reserved
14	Reserved
15	Reserved
16-31	Reserved

Table 62. DAI Control, Data and Status Register Locations (cont.)

6.23.4.1 *Right Channel Transmit FIFO Service Request Flag (RCTS)*

The Right Channel Transmit FIFO Service Request Flag (RCTS) is a read-only bit which is set when the Right Channel Transmit FIFO is nearly empty and requires service to prevent an underrun. RCTS is set any time the Right Channel Transmit FIFO has four or fewer entries of valid data (half full or less), and is cleared when it has five or more entries of valid data. When the RCTS bit is set, an interrupt request is made unless the Right Channel Transmit FIFO interrupt request mask (RCTM) bit is cleared. After the CPU fills the FIFO such that four or more locations are filled within the Right Channel Transmit FIFO, the RCTS flag (and the service request and / or interrupt) is automatically cleared.

6.23.4.2 *Right Channel Receive FIFO Service Request Flag (RCRS)*

The Right Channel Receive FIFO Service Request Flag (RCRS) is a read-only bit which is set when the Right Channel Receive FIFO is nearly filled and requires service to prevent an overrun. RCRS is set any time the Right Channel Receive FIFO has six or more entries of valid data (half full or more), and cleared when it has five or fewer (less than half full) entries of data. When the RCRS bit is set, an interrupt request is made unless the Right Channel Receive FIFO interrupt request mask (RCRM) bit is cleared. After six or more entries are removed from the receive FIFO, the RCRS flag (and the service request and / or interrupt) is automatically cleared.

6.23.4.3 *Left Channel Transmit FIFO Service Request Flag (LCTS)*

The Left Channel Transmit FIFO Service Request Flag (LCTS) is a read-only bit which is set when the Left Channel Transmit FIFO is nearly empty and requires service to prevent an underrun. LCTS is set any time the Left Channel Transmit FIFO has four or fewer entries of valid data (half full or less). It is cleared when it has five or more entries of valid data. When the LCTS bit is set, an interrupt request is made unless the Left Channel Transmit FIFO interrupt request mask (LCTM) bit is cleared. After the CPU fills the FIFO such that four or more locations are filled within the Left Channel Transmit FIFO, the LCTS flag (and the service request and / or interrupt) is automatically cleared.

6.23.4.4 *Left Channel Receive FIFO Service Request Flag (LCRS)*

The Left Channel Receive FIFO Service Request Flag (LCRS) is a read-only bit which is set when the Left Channel Receive FIFO is nearly filled and requires service to prevent an overrun. LCRS is set any time the Left Channel Receive FIFO has six or more entries of valid data (half full or more), and cleared when it has five or fewer (less than half full) entries of data. When the LCRS bit is set, an interrupt request is made unless the Left Channel Receive FIFO interrupt request mask (LCRM) bit is cleared. After six or more entries are removed from the receive FIFO, the LCRS flag (and the service request and / or interrupt) is automatically cleared.

6.23.4.5 *Right Channel Transmit FIFO Underrun Status (RCTU)*

The Right Channel Transmit FIFO Underrun Status Bit (RCTU) is set when the Right Channel Transmit logic attempts to fetch data from the FIFO after it has been completely emptied. When an underrun occurs, the Right Channel Transmit logic continuously transmits the last valid right channel value which was transmitted before the underrun occurred. Once data is placed in the FIFO and it is transferred down to the bottom, the Right Channel Transmit logic uses the new value within the FIFO for transmission. When the RCTU bit is set, an interrupt request is made.

6.23.4.6 *Right Channel Receive FIFO Overrun Status (RCRO)*

The Right Channel Receive FIFO Overrun Status Bit (RCRO) is set when the right channel receive logic attempts to place data into the Right Channel Receive FIFO after it has been completely filled. Each time a new piece of data is received, the set signal to the RCRO status bit is asserted, and the newly received data is discarded. This process is repeated for each new sample received until at least one empty FIFO entry exists. When the RCRO bit is set, an interrupt request is made.

6.23.4.7 *Left Channel Transmit FIFO Underrun Status (LCTU)*

The Left Channel Transmit FIFO Underrun Status Bit (LCTU) is set when the Left Channel Transmit logic attempts to fetch data from the FIFO after it has been completely emptied. When an underrun occurs, the Left Channel Transmit logic continuously transmits the last valid left channel value which was transmitted before the underrun occurred. Once data is placed in the FIFO and it is transferred down to the bottom, the Left Channel Transmit logic uses the new value within the FIFO for transmission. When the LCTU bit is set, an interrupt request is made.

6.23.4.8 *Left Channel Receive FIFO Overrun Status (LCRO)*

The Left Channel Receive FIFO Overrun Status Bit (LCRO) is set when the Left Channel Receive logic places data into the Left Channel Receive FIFO after it has been completely filled. Each time a new piece of data is received, the set signal to the LCRO status bit is asserted, and the newly received sample is discarded. This process is repeated for each new piece of data received until at least one empty FIFO entry exists. When the LCRO bit is set, an interrupt request is made.

6.23.4.9 *Right Channel Transmit FIFO Not Full Flag (RCNF)*

The Right Channel Transmit FIFO Not Full Flag (RCNF) is a read-only bit which is set whenever the Right Channel Transmit FIFO contains one or more entries which do not contain valid data and is cleared when the FIFO is completely full. This bit can be polled when using programmed I/O to fill the Right Channel Transmit FIFO. This bit does not request an interrupt.

6.23.4.10 *Right Channel Receive FIFO Not Empty Flag (RCNE)*

The Right Channel Receive FIFO Not Empty Flag (RCNELCNF) is a read-only bit which is set when ever the Right Channel Receive FIFO contains one or more entries of valid data and is cleared when it no longer contains any valid data. This bit can be polled when using programmed I/O to remove remaining data from the receive FIFO. This bit does not request an interrupt.

6.23.4.11 *Left Channel Transmit FIFO Not Full Flag (LCNF)*

The Left Channel Transmit FIFO Not Full Flag (LCNF) is a read-only bit which is set when ever the Left Channel Transmit FIFO contains one or more entries which do not contain valid data. It is cleared when the FIFO is completely full. This bit can be polled when using programmed I/O to fill the Left Channel Transmit FIFO. This bit does not request an interrupt.

6.23.4.12 *Left Channel Receive FIFO Not Empty Flag (LCNE)*

The Left Channel Receive FIFO Not Empty Flag (LCNE) is a read-only bit which is set when ever the Left Channel Receive FIFO contains one or more entries of valid data and is cleared when it no longer contains any valid data. This bit can be polled when using programmed I/O to remove remaining data from the receive FIFO. This bit does not request an interrupt.

6.23.4.13 *FIFO Operation Completed Flag (FIFO)*

The FIFO Operation Completed (FIFO) Flag is set after the FIFO operation requested by writing to DAIDR2 as completed.

FIFO is automatically cleared when DAIDR2 is read or written. This bit does not request an interrupt.
