➤ **To remove a storage assigned to a VM:**

**Step 1.** Remove the VM assigned the disk space. Run:

```
switch (config) # no virtual-machine host my-vm
```

**Step 2.** Remove the disk space assigned to that VM. Run:

```
switch (config) # no virtual-machine volume file mydisk.img
```

## 4.19.2 Commands

### 4.19.2.1 Config

#### virtual-machine enable

**virtual-machine enable**  
**no virtual-machine enable**

Enables VM feature on the switch.  
The no form of the command disables VM feature on the switch.

| <b>Example</b>            | switch (config) # virtual-machine enable |
| <b>Related Commands</b>   |                                          |
| <b>Note</b>               |                                          |

## virtual-machine host

**virtual-machine host <vm-name>**  
**no virtual-machine host <vm-name>**

Creates a VM, or enters its configuration context if it already exists.  
 The no form of the command removes the VM of the specified name.

|                           |                                                                                                    |                               |

| <b>Note</b>               |                                                                                                    |                               |

## arch

**arch {i386 | x86\_64}**

Configures VM CPU architecture.

|                           |                                                       |                             |
|---------------------------|-------------------------------------------------------|-----------------------------|
| <b>Syntax Description</b> | i386                                                  | 32-bit x86 CPU architecture |
|                           | x86_64                                                | 64-bit x86 CPU architecture |
| <b>Default</b>            | x86_64                                                |                             |
| <b>Configuration Mode</b> | Config Virtual Machine Host                           |                             |
| <b>History</b>            | 3.4.0000                                              |                             |
| <b>Role</b>               | admin                                                 |                             |
| <b>Example</b>            | switch (config virtual-machine host my-vm)# arch i386 |                             |
| <b>Related Commands</b>   | virtual-machine                                       |                             |
| <b>Note</b>               |                                                       |                             |

## comment

**comment** <string>

**no comment**

Configures a comment describing the VM.

The no form of the command deletes the configured comment.

|                           |                                                                                     |             |

| <b>Example</b>            | switch (config virtual-machine host my-vm)# comment "example VM"                    |             |
| <b>Related Commands</b>   | virtual-machine                                                                     |             |
| <b>Note</b>               | To configure a multi-word string, the string must be placed within quotation marks. |             |

## console

**console {connect [graphics | text [force]] | graphics vnc | text tty}**  
**no console {graphics vnc | text tty}**

Configures or connects to a text or graphical console.  
 The no form of the command clears console settings.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                                                                                                                                |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>To exit the text console press Ctrl-6 (or Ctrl-Shift-6)</li> <li>If the guest OS is not configured to receive input from a serial console (ttyS0), the VM console becomes unresponsive when connected to.</li> <li>To view the graphical console, X display must be enabled. There are two options to activate it, the command <code>vncviewer -via admin@&lt;switchIP&gt; 127.0.0.1:&lt;VNC display num&gt;</code> (which is run from an external Linux host) and the command <code>ssh server x11-forwarding enable</code> (which is run from within the switch and requires that you log out and log back in again using <code>ssh -X</code>). The latter command weakens the switch security, therefore, it is recommended to opt for the second option. The VNC display num parameter may be procured by running the command <code>show virtual-machine &lt;vm-name&gt; detail</code>.</li> </ul> |                                                                                                                                                                                                                |

## install

**install {cancel | cdrom [pool <pool-name>] {file <volume-name> [connect-console <console-type> | disk-overwrite | timeout {<minutes> | none}]}}**

Installs an operating system onto this VM (temporarily attach a CD and boot from it).

| <b>Related Commands</b>   | virtual-machine                                                      |                                                                                                                                                              |
| <b>Note</b>               |                                                                      |                                                                                                                                                              |

## memory

### memory <MB>

Configures memory allowance.

|                           |                                                                   |                    |
|---------------------------|-------------------------------------------------------------------|--------------------|
| <b>Syntax Description</b> | MB                                                                | Size in megabytes. |
| <b>Default</b>            | 512MB                                                             |                    |
| <b>Configuration Mode</b> | Config Virtual Machine Host                                       |                    |
| <b>History</b>            | 3.4.0000                                                          |                    |
| <b>Role</b>               | admin                                                             |                    |
| <b>Example</b>            | switch (config virtual-machine host my-vm)# memory 1024           |                    |
| <b>Related Commands</b>   | virtual-machine                                                   |                    |
| <b>Note</b>               | It is recommended not to allocate more than 1GB of memory per VM. |                    |

## power

**power {cycle [force | connect-console {graphics | text}] | off [force] | on [connect-console {graphics | text}]}**

Turns the VM on or off, or other related options.

|                           |                                                               |                                                                                                                                                                           |
|---------------------------|---------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | cycle                                                         | Powers the VM down and then on again immediately                                                                                                                          |
|                           | force                                                         | Forces an action on the system.                                                                                                                                           |
|                           | connect-console <console-type>                                | Connects to the console after power-on. The types may be: <ul style="list-style-type: none"> <li>• text – text console</li> <li>• graphics – graphical console</li> </ul> |
|                           | off                                                           | Powers down the VM                                                                                                                                                        |

## storage create

**storage create disk** [**drive-number** <number> | **file** <filename> | **mode** {read-only | read-write} | **pool** <pool-name> | **size-max** <MB>]

Creates a new storage device for the VM, with an automatically assigned name.

|                           |                                                                               |                                                                                                                   |

## storage device

**storage device** [bus ide] drive-number <number> [mode {read-only | read-write}] source {[pool <pool-name>] file <filename>}  
**no storage device** [bus ide] drive-number <id>

Modifies existing storage device, or create a new one with a specific name.  
 The no form of the command removes a storage device from the VM.

## vcpus

**vcpus {count <count> | vcpu <vcpu> pin <cpu-list> [<cpu-list>]}**  
**no vcpus {pin | vcpu <vcpu> pin}**

Specifies virtual CPUs.

The no form of the command removes certain CPU configuration.

## virtual-machine volume fetch url

**virt volume fetch url** <download-url> [filename <filename> | pool <pool-name> filename <filename>]

Fetches volume image from a remote host.

|                           |                                                                                                  |                                                                                                                                                                |

## virt volume file

**virt volume file <name> {create disk size-max <MB> | move {new-name <new-name> | pool <pool-name> new-name <new-name>} | upload <upload-url>}  
no virt volume file <volume-name>**

Specifies name of volume file to manage.  
The no form of the command deletes the volume file.

## 4.20 Back-Up Battery Units

The back-up battery unit (BBUs) is an optional field replaceable unit installed inside the power supply unit (PSU) which provides power to the platform. The BBU is a hardware feature which provides energy in case the main and, if equipped, the back-up PSUs fail.

The BBU provides power outage for a limited time which allows time for performing controlled shutdown or recovering the main power source of the system, or connecting to a new power source.

When the switch system is plugged in to a power source, the BBU may be configured to charge in preparation for possible power outage scenarios.

Switching from the main power source to the BBU and vice versa does not interfere with the normal operation of the switch system.

The only switch system featuring BBUs is SX6720.

## 4.20.1 Commands

### battery-backup-unit charge

**battery-backup-unit charge {bbu1 | bbu2 | all}**  
**no battery-backup-unit charge {bbu1 | bbu2 | all}**

Enables charging the BBU.  
 The no form of the command disables charging the BBU.

## battery-backup-unit discharge

**battery-backup-unit discharge {bbu1 | bbu2 | all}**  
**no battery-backup-unit discharge {bbu1 | bbu2 | all}**

Enables discharging the BBU in case of power outage.  
 The no form of the command disables discharging the BBU in case of power outage.

## 5 Ethernet Switching

### 5.1 Interface

Interface Ethernet have the following physical set of configurable parameters

- Admin state – enabling or disabling the interface
- Flow control – admin state per direction (send or receive)
- MTU (Maximum Transmission Unit) – 1500-9216 bytes
- Speed – 1/10/40/56GbE (depends on the interface type and system)
- Description – user defined string
- Module-type – the type of the module plugged in the interface

To use 40GbE QSFP interfaces as 10GbE (via QSA adapter), the speed must be manually set with the command “speed 10000” under the interface configuration mode.

#### 5.1.1 Break-Out Cables

The break-out cable is a unique Mellanox capability, where a single physical 40Gbps port is divided into 2x10Gbps or 4x10Gbps ports. It maximizes the flexibility of the end user to use the Mellanox switch with a combination of 10Gbps and 40Gbps interfaces according to the specific requirements of its network. Certain ports cannot be split at all and there are ports which can be split into 2 ports only. Splitting a port changes the notation of that port from x/y to x/y/z with “x/y” indicating the previous notation of the port prior to the split and “z” indicating the number of the resulting 10G port (1,2 or 1,2,3,4). Each sub-physical port is then handled as an individual port. For example: splitting port 10 into 4 will give the following new ports: 1/10/1, 1/10/2, 1/10/3, 1/10/4.

**Figure 16: Break-Out Cable**

A split-4 operation results in blocking a 40G port in addition to the one being split. A set of hardware restrictions determine which of the ports can be split.

Specific ports can be split by using a QSFP 1X4 breakout cable to split one 40 Gb/s port into 4 lanes (4 SFP+ connectors). These 4 lanes then go, one lane to each of the 4 SFP+ connectors. Some ports can be split into 2 10 Gb/s ports, using lanes 1 and 2 only. When a QSFP port is split into 2 10Gb/s ports then only SFP+ connectors #1 and #2 are used. Connectors #3 and #4 are left unconnected.

Splitting the interface deletes all configuration on that interface.

When splitting an interface's traffic into 4 10Gb/s data streams (four lanes) one of the other ports on the switch must be disabled (unmapped).

- some ports can be split into 4
- some ports can be split into 2
- some ports become unmapped due to a 1X4 split

**Figure 17: Port Splitting Options**

This port can be split into 4 10Gb/s SFP+

This port can be split into 2 10Gb/s SFP+

This port is unmapped by the neighboring split 4 port

The maximum number of 10 Gb/s Ethernet ports configurable with this switch is 34.

**Table 50 - Port Splitting Options**

| Port # | Can be split to 4 | Turns off port # | Can be split to 2 | Port # | Can be split to 4 | Turns off port # | Can be split to 2 |
|--------|-------------------|------------------|-------------------|--------|-------------------|------------------|-------------------|
|        | —                 |                  | YES               |        | YES               |                  | —                 |
|        | —                 |                  | —                 |        | —                 |                  | —                 |
|        | YES               |                  | —                 |        | —                 |                  | —                 |
|        | —                 |                  | YES               |        | YES               |                  | —                 |
|        | —                 |                  | —                 |        |                   |                  | —                 |
|        | YES               |                  | —                 |        |                   |                  | YES               |
|        | —                 |                  | —                 |        | YES               |                  | —                 |
|        | —                 |                  | —                 |        | —                 |                  | —                 |
|        | YES               |                  | —                 |        | —                 |                  | YES               |

To see the exact splitting options available per system, refer to each specific system's hardware user manual (Cabling chapter) located on the Mellanox website.

### 5.1.1.1 Changing the Module Type to a Split Mode

➤ *To split an interface:*

**Step 1.** Shut down all the ports related to the interface. Run:

- in case of split-2, shut down the current interface only
- in case of split-4, shut down the current interface and the other interface according to the table above

```
switch (config) # interface ethernet 1/1
switch (config interface ethernet 1/1) # shutdown
switch (config interface ethernet 1/1) # exit
switch (config) # interface ethernet 1/4
switch (config interface ethernet 1/4) # shutdown
```

**Step 2.** Split the ports as desired. Run:

```
switch (config interface ethernet 1/4) # module-type qsfp-split-4
switch (config interface ethernet 1/4) #
```

**Step 3.** The following warning will be displayed:  
the following interfaces will be unmapped: 1/4 1/1.  
Choose Yes when prompted Type 'yes' to confirm split

The <ports> field in the warning refers to the affected ports from splitting port <inf> in the applied command.

Please beware that splitting a port into 4 prevents you from accessing the splittable port, and an additional one. For example, in the procedure above, ports 3 and 4 become inaccessible.

### 5.1.1.2 Unsplitting a Split Port

➤ *To unsplit a split port:*

**Step 1.** Shut down all of the split ports. Run:

```
switch (config interface ethernet 1/4/4) # shutdown
switch (config interface ethernet 1/4/4) # exit
switch (config) # interface ethernet 1/4/3
switch (config interface ethernet 1/4/3) # shutdown
switch (config interface ethernet 1/4/3) # exit
switch (config) # interface ethernet 1/4/2
switch (config interface ethernet 1/4/2) # shutdown
switch (config interface ethernet 1/4/2) # exit
switch (config) # interface ethernet 1/4/1
switch (config interface ethernet 1/4/1) # shutdown
```

**Step 2.** From the first member of the split (1/4/1), change the module-type back to QSFP. Run:

```
switch (config interface ethernet 1/4/1) # module-type qsfp
```

The module-type can be changed **only** from the first member of the split and **not** from the interface that was split.

The following warning will be displayed:

The following interfaces will be unmapped: 1/4/1 1/4/2 1/4/3 1/4/4.

**Step 3.** Type “yes” when prompted “Type 'yes' to confirm unsplit.”

### 5.1.2 56GbE Link Speed

Mellanox offers proprietary speed of 56Gbps per Ethernet interface. 56GbE speed is achievable only on 1U Infiniband FDR system (i.e. SX6036F, SX1024, and SX1036).

The following OPNs support 56GbE:

- MSX6036F-xxxx
- MSX1036x-xxxS
- MSX1024x-xxxS
- MSX1012x-xxxx
- MSX6012F-xxxx
- MSX6018F-xxxx

The following OPNs do not support 56GbE:

- MSX6036T-xxxx
- MSX1036x-xxxR
- MSX6012T-xxxx
- MSX6018T-xxxx

#### ➤ *To achieve 56GbE link speed:*

**Step 1.** Make sure your system is 1U FDR capable (i.e. SX6036F, SX1024, and SX1036).

56GbE can only be achieved on 1U FDR capable systems.

**Step 2.** Install 56GbE license. Run:

```
switch (config) # license install <license key>
```

**Step 3.** Install Ethernet license. Run:

```
switch (config) # license install <license key>
```

For a list of the available licenses see [Section 2.4, “Licenses,”](#) on page 39.

**Step 4.** Set the system profile to be eth-single-switch, and reset the system:

```
switch (config) # system profile eth-single-profile
```

**Step 5.** Set the speed for the desired interface to 56GbE as follows. Run:

```
switch (config) # interface ethernet 1/1
switch (config interface ethernet 1/1) # speed 56000
switch (config interface ethernet 1/1) #
```

**Step 6.** Verify the speed is 56GbE

```

switch (config) # show interface ethernet 1/1
Eth1/1
Admin state: Enabled
Operational state: Down
Description: N\A
Mac address: 00:02:c9:5d:e0:26
MTU: 1522 bytes
Flow-control: receive off send off
Actual speed: 56 Gbps
Switchport mode: access
Rx
0 frames
0 unicast frames
0 multicast frames
0 broadcast frames
0 octets
0 error frames
0 discard frames
Tx
0 frames
0 unicast frames
0 multicast frames
0 broadcast frames
0 octets
0 discard frames
switch (config) #

```

**5.1.3 Transceiver Information**

MLNX-OS offers the option of viewing the transceiver information of a module or cable connected to a specific interface. The information is a set of read-only parameters burned onto the EEPROM of the transceiver by the manufacture. The parameters include identifier (connector type), cable type, speed and additional inventory attributes.

➤ **To display transceiver information of a specific interface, run:**

```

switch (config) # show interfaces ethernet 1/60 transceiver
Port 1/60 state
 identifier : QSFP+
 cable/ module type : Passive copper, unequalized
 ethernet speed and type: 56GigE
 vendor : Mellanox
 cable length : 1m
 part number : MC2207130-001
 revision : A3
 serial number : MT1238VS04936
switch (config) #

```

The indicated cable length is rounded up to the nearest natural number.

### 5.1.4 High Power Transceivers

Mellanox switch systems offer high power transceiver (LR4) support in the following ports:

- SX1036/SX1700 – ports 1, 3, 33, 35
- SX1024/SX1400 – ports 50, 52, 54, 56, 58, 60
- SX1012/SX1710 – all ports

If a high power transceiver (e.g. LR4) is inserted to a port that does not support it, the link does not go up, and the following warning message is displayed: “Warning: High power transceiver is not supported” when the command “show interfaces ethernet” is run.

## 5.1.5 Commands

### interface ethernet

**interface ethernet** <slot>/<port>[/<subport>]-[<slot>/<port>[/<subport>]]

Enters the Ethernet interface or Ethernet interface range configuration mode.

|                           |                                                                                                                                                                                               |                                                            |

## mtu

### mtu <frame-size>

Configures the Maximum Transmission Unit (MTU) frame size for the interface.

|                           |                                                                                                  |                                            |
|---------------------------|--------------------------------------------------------------------------------------------------|--------------------------------------------|
| <b>Syntax Description</b> | frame-size                                                                                       | This value may be 1500-9216 bytes.         |
| <b>Default</b>            | 1522 bytes                                                                                       |                                            |

## shutdown

**shutdown**  
**no shutdown**

Disables the interface.  
 The no form of the command enables the interface.

|                           |                                                                                                  |

## speed

**speed <port speed> [force]**

**no speed**

Sets the speed of the interface.

The no form of the command sets the speed of the interface to its default value.

|                           |                                                                                                                                                                                                                                                                                                       |                                                                |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• 56Gbps port speed requires a license (LIC-6036F-56GE)</li> <li>• The default speed depends on the interface capabilities, interface capable with 40Gbps will have 40Gbps speed by default</li> <li>• Not all interfaces support all speed options</li> </ul> |                                                                |

## load-interval

**load-interval <time>**

**no load-interval**

Sets the interface counter interval.

The no form of the command resets the interval to its default value.

|                           |                                                                                                       |                                            |

## show interfaces ethernet

**show interfaces ethernet <inf> [counters [priority]]**

Displays the configuration and status for the interface.

|                           |          |                                                          |
|---------------------------|----------|----------------------------------------------------------|
| <b>Syntax Description</b> | inf      | Interface number: <slot>/<port>.                         |
|                           | counters | Displays interface extended counters.                    |
|                           | priority | Displays interface extended counters per priority (0-7). |
| <b>Default</b>            | N/A      |                                                          |

**Configuration Mode** Any Command Mode

**History** 3.1.0000

**Role** admin

**Example**

```
switch (config) # show interfaces ethernet 1/1

Eth1/1

Admin state: Enabled
Operational state: Up
Description: N/A
Mac address: 00:02:c9:71:ed:2d
MTU: 1500 bytes(Maximum packet size 1522 bytes)
Flow-control: receive off send off
Actual speed: 40 Gbps
Width reduction mode: Not supported
Switchport mode: access
Last clearing of "show interface" counters 00:20:39
60 seconds Ingress rate: 0 bits/sec, 0 bytes/sec, 0 packets/sec
60 seconds Egress rate: 0 bits/sec, 0 bytes/sec, 0 packets/sec

Rx
 0 packets
 0 unicast packets
 0 multicast packets
 0 broadcast packets
 0 bytes
 0 error packets
 0 discard packets

Tx
63 packets
 0 unicast packets
63 multicast packets
 0 broadcast packets
4032 bytes
 0 discard packets

switch (config) #
```

## 5.2 Link Aggregation Group (LAG)

Link Aggregation protocol describes a network operation in which several same speed links are combined into a single logical entity with the accumulated bandwidth of the originating ports. LAG groups exchange Lag Aggregation Control Protocol (LACP) packets in order to align the functionality between both endpoints of the LAG. To equally send traffic on all LAG links, the switch uses a hash function which can use a set of attributes as key to the hash function.

As many as 16 physical ports can be aggregated on a single LAG.

### 5.2.1 Configuring Static Link Aggregation Group (LAG)

➤ *To configure a static LAG:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a port-channel entity. Run:

```
switch (config) # interface port-channel 1
switch (config interface port-channel 1) #
```

**Step 4.** Change back to config mode.

```
switch (config interface port-channel 1) # exit
switch (config) #
```

**Step 5.** Add a physical port to the port-channel. Run:

```
switch (config interface ethernet 1/4) # channel-group 1 mode on
switch (config interface ethernet 1/4) #
```

If the physical port is operationally up, this port becomes an active member of the aggregation. Consequently, it becomes able to convey traffic.

### 5.2.2 Configuring Link Aggregation Control Protocol (LACP)

➤ *To configure LACP:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a port-channel entity. Run:

```
switch (config) # interface port-channel 1
switch (config interface port-channel 1) #
```

**Step 4.** Change back to config mode. Run:

```
switch (config interface port-channel 1) # exit
switch (config) #
```

**Step 5.** Enable LACP in the switch. Run:

```
switch (config) # lacp
switch (config) #
```

**Step 6.** Add a physical port to the port-channel. Run:

```
switch (config interface ethernet 1/4) # channel-group 1 mode active/passive
switch (config interface ethernet 1/4) #
```

## 5.2.3 Commands

### interface port-channel

**interface port-channel** <1-4096>[-<2-4096>]  
**no interface port-channel** <1-4096>[-<2-4096>]

Creates a LAG and enters the LAG configuration mode. There is an option to create a range of LAG interfaces.

The no form of the command deletes the LAG, or range of LAGs.

| Note               | Configuring LACP rate (fast or slow) will configure the peer port to send (fast or slow), it does not make any affect on the local port LACP rate.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                 |           |          |                    |            |          |             |            |     |      |     |   |   |     |     |

## port-channel load-balance ethernet

**port-channel load-balance ethernet <method>**  
**no port-channel load-balance ethernet <method>**

Configures the port-channel load balancing distribution function method.  
 The no form of the command sets the distribution function method to default.

## channel-group

**channel-group** <1-4096> [mode {on | active | passive}]

**no channel-group**

Assigns and configures a physical interface to a port channel.

The no form of the command removes a physical interface from the port-channel.

The port with a different configuration will be rejected, for the list of dependencies refer to ‘show interfaces port-channel compatibility-parameters’</li> <li>A physical port may only be part of one channel-group</li> </ul> |                                                                                               |

## lacp-individual enable

**lacp-individual enable [force]**  
**no lacp-individual enable [force]**

Configures the LAG to act with LACP-individual capabilities.  
 The no form of the command disables the LACP-individual capability.

**Example**

```

switch (config) # show lacp interfaces neighbor
Flags:
A - Device is in Active mode
P - Device is in Passive mode

Channel group 1 neighbors

Port 1/4

Partner System ID : 00:00:00:00:00:00
Flags : A
LACP Partner Port Priority : 0
LACP Partner Oper Key : 0
LACP Partner Port State : 0x0

Port State Flags Decode

Activity : Active
Aggregation State : Aggregation, Sync, Collecting, Distributing

MLAG channel group 25 neighbors

Port 1/49

Partner System ID : 00:02:c9:fa:c4:c0
Flags : A
LACP Partner Port Priority : 255
LACP Partner Oper Key : 33
LACP Partner Port State : 0xbc

Port State Flags Decode

Activity : Active
Aggregation State : Aggregation, Sync, Collecting, Distributing,

MLAG channel group 28 neighbors

Port 1/51

Partner System ID : f4:52:14:10:d8:f1
Flags : A
LACP Partner Port Priority : 255
LACP Partner Oper Key : 33
LACP Partner Port State : 0xbc

Port State Flags Decode

Activity : Active
Aggregation State : Aggregation, Sync, Collecting, Distributing,

switch (config) #

```

**Related Commands****Note**

## show lacp

### show lacp

Displays the LACP global parameters.

## 5.3 MLAG

All nodes in an MLAG must be of the same CPU type (i.e. PPC or x86).

Each switch configuration is independent and it is user responsibility to make sure to configure both switches similarly pertaining MLAG (e.g. MLAG port-channel VLAN membership, static MAC, ACL, etc).

A link aggregation group (LAG) is used for extending the bandwidth from a single link to multiple links and provide redundancy in case of link failure. Extending the implementation of the LAG to more than a single device provides yet another level of redundancy that extends from the link level to the node level. This extrapolation of the LAG from single to multiple switches is referred to as multi-chassis link aggregation (MLAG).

MLAG is currently supported for only 2 switches.

A peered device (host or switch) connecting to switches running an MLAG runs a standard LAG and is unaware of the fact that the LAG connects to two separate switches.

MLAG links currently mandate disabling xSTP control protocol. However, interfaces not part of an MLAG can run any protocol independently.

The MLAG switches share an inter-peer link (IPL) between them for carrying control messages in a steady state or data packages in failure scenarios. Thus, the bandwidth of the IPL should be

defined accordingly. The IPL itself can be a LAG and be constructed of either 10GbE or 40GbE links. In such a case, PFC must be configured on this IPL. [Figure 19, “Basic MLAG Topology,” on page 540](#) illustrates. The IPL serves the following purposes:

- MLAG protocol control – keepalive messages, MAC sync, MLAG port sync, etc.
- MLAG port failure – serves redundancy in case of a fallen link on one of the MLAG switches.
- Layer-3 failure – serves redundancy in case of a failed connection between the MLAG switches and the rest of the L3 network should there be one.

The MLAG protocol is made up of the following components to be expanded later:

- Keepalive
- Unicast and multicast sync
- MLAG port sync

Upgrading software of an MLAG pair can be done without consideration for master/slave roles. Switches in the same MLAG group must have the same MLNX-OS version.

When positioned at the top of rack (ToR) and connecting with a Layer-3 uplink, the MLAG pair acts as the L3 border for the hosts connected to it. To allow default gateway redundancy, both MLAG switches should be addressed by the host via the same default gateway address.

MLAG uses an IP address (VIP) that is always directed to the MLAG-VIP master node.

When running MLAG with L3, VRRP or MAGP must be deployed. For more information, refer to [Section 6.7, “VRRP,” on page 961](#) or [Section 6.8, “MAGP,” on page 976](#) respectively.

When MLAG is connected through a Layer-2 based uplink, there is no need to apply default gateway redundancy towards hosts since this function is implemented on the L2/L3 border points of the network.

The two peer switches need to carry the exact same configuration of the MLAG attributes for guaranteeing proper functionality of the MLAG.

Ensuring that both switches are configured identically is the responsibility of the user and is not monitored by the MLNX-OS software.

When working with MLAG the maximum number of MAC addresses is limited to 47,970. Without it, the number of MAC addresses would be 55,872.

When transitioning from standalone into a group or vice versa, a few seconds are required for the node state to stabilize. During that time, group features such as Gateway HA, SM HA, and MLAG commands should not be executed. To run group features, wait for the CLI prompt to turn into [standalone:master], [<group>:master] or [<group>:standby] instead of [standalone:\*unknown\*] or [<group>:\*unknown\*].

### 5.3.1 MLAG Keepalive and Failover

Master election in MLAG is based on the IPs of the nodes taking part of the MLAG. The master elected is that which has the higher IPL VLAN Interface.

The MLAG pair of switches periodically exchanges a keepalive message on a user configurable interval. If the keepalive message fails to arrive for three consecutive intervals the switches break into two standalone switches. In such case the remaining active switch begins to act as a standalone switch and assumes that its previously peering MLAG switch has failed.

To avoid a scenario where failure on the IPL causes both MLAG peers to assume that their peer has failed, a safety mechanism based on UDP packets running via the management plane is maintained and alerts both peers of IPL failure. In such a case of IPL failure, the slave shuts down its interfaces to avoid a split brain scenario and the master becomes a standalone switch.

### 5.3.2 Unicast and Multicast Sync

Unicast and multicast sync is a mechanism which syncs the unicast and multicast FDBs of the MLAG peers. It prevents unicast asymmetric traffic from loading the network with flood traffic and multicast traffic from being processed.

### 5.3.3 MLAG Port Sync

Under normal circumstances, traffic from the IPL cannot pass through the MLAG ports (the IPL is isolated from the MLAG ports). If one of the MLAG links break, the other MLAG switch opens that isolation and allows traffic from its peer through the IPL to flow via the MLAG port which accesses the destination of the fallen link.

### 5.3.4 MLAG Configuration

This section provides an example of how to configure two switches and a server in an MLAG setup.

➤ **To configure L2 MLAG:**

Prerequisites:

**Step 1.** Enable IP routing. Run:

```
switch (config)# ip routing
```

**Step 2.** (Recommended) Enable LACP in the switch. Run:

```
switch (config)# lacp
```

**Step 3.** Enable QoS on the switch to avoid congestion on the IPL port. Run:

```
switch (config)# dcb priority-flow-control enable force
```

**Step 4.** Enable the MLAG protocol commands. Run:

```
switch (config)# protocol mlag
```

Configuring the IPL:

**Step 1.** Create a VLAN for the inter-peer link (IPL) to run on. Run:

```
switch (config)# vlan 4000
switch (config vlan 4000)#
```

**Step 2.** Create a LAG. Run:

```
switch (config)# interface port-channel 1
switch (config interface port-channel 1)#
```

**Step 3.** Map a physical port to the LAG in active mode (LACP). Run:

```
switch (config)# interface ethernet 1/1 channel-group 1 mode active
```

**Step 4.** Set this LAG as an IPL. Run:

```
switch (config interface port-channel 1)# ipl 1
```

**Step 5.** Enable QoS on this specific interface. Run:

```
switch (config interface port-channel 1)# dcb priority-flow-control mode on force
```

**Step 6.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 4000
switch (config interface vlan 4000)#
```

**Step 7.** Set an IP address and netmask for the VLAN interface.

On SwitchA, run:

```
switch (config interface vlan 4000)# ip address 10.10.10.1 /30
```

On SwitchB, run:

```
switch (config interface vlan 4000)# ip address 10.10.10.2 /30
```

**Step 8.** Map the VLAN interface to be used on the IPL and set the peer IP address (the IP address of the IPL port on the second switch) of the IPL peer port. IPL peer ports must be configured on the same netmask.

On SwitchA, run:

```
switch (config interface vlan 4000)# ipl 1 peer-address 10.10.10.2
```

On SwitchB, run:

```
switch (config interface vlan 4000)# ipl 1 peer-address 10.10.10.1
```

**Step 9.** Configure a virtual IP (VIP) for the MLAG. Run:

On SwitchA, run:

```
switch (config)# mlag-vip my-vip ip 10.10.10.254 /24 //mask may also be 255.255.255.0
```

On SwitchB, run:

```
switch (config)# mlag-vip my-vip
```

**Step 10.** Configure a virtual system MAC for the MLAG. Run:

```
switch (config)# mlag system-mac 00:00:5E:00:01:5D
```

#### Creating an MLAG interface:

**Step 1.** Create an MLAG interface for the host. Run:

```
switch (config)# interface mlag-port-channel 1
switch (config interface mlag-port-channel 1)#
```

**Step 2.** Disable STP. Run:

```
switch (config interface mlag-port-channel 1)# spanning-tree port type edge
switch (config interface mlag-port-channel 1)# spanning-tree bpdufilter enable
```

**Step 3.** Bind an Ethernet port to the MLAG group. Run:

```
switch (config interface ethernet 1/2)# mlag-channel-group 1 mode on
```

**Step 4.** Create and enable the MLAG interface. Run:

```
switch (config interface mlag-port-channel 1)# no shutdown
```

STP must be disabled (no spanning-tree) on the MLAG switches when there is at least 1 MLAG port-channel connected to a switch and not to a host.

Enabling MLAG:**Step 1.** Enable MLAG. Run:

```
switch [my-vip: master] (config mlag)# no shutdown
```

When running MLAG with L3, VRRP or MAGP must be deployed. For more information, refer to [Section 6.7, “VRRP,”](#) on page 961 or [Section 6.8, “MAGP,”](#) on page 976 respectively.

➤ **To verify MLAG configuration:****Step 1.** Examine MLAG configuration and status. Run:

```
SX2 [mellanox: master] (config)# show mlag
Admin status: Enabled
Operational status: Up
Reload-delay: 1 sec
Keepalive-interval: 30 sec
Upgrade-timeout: 60 min
System-mac: 00:00:5E:00:01:5D

MLAG Ports Configuration Summary:
Configured: 1
 Disabled: 0
 Enabled: 1

MLAG Ports Status Summary:
Inactive: 0
Active-partial: 0
Active-full: 1

MLAG IPLs Summary:
ID Group Vlan Operational Local Peer
 Port-Channel Interface State IP address IP address

1 Po1 1 Up 10.10.10.1 10.10.10.2

Peers state Summary:
System-id State Hostname

F4:52:14:2D:9B:88 Up <SX2>
F4:52:14:2D:9B:08 Up SX1
switch [mellanox: master] (config)#
```

**Step 2.** Examine the MLAG summary table. Run:

```
switch [my-vip: master] (config)# show interfaces mlag-port-channel summary
MLAG Port-Channel Flags: D-Down, U-Up
P-Partial UP, S - suspended by MLAG
Port Flags: D - Down, P - Up in port-channel (members)
S - Suspend in port-channel (members), I - Individual
Group
Port-Channel Type Local Ports Peer Ports
(D/P/S/I) (D/P/S/I) (D/P/S/I)

1 Mpo2(U) Static Eth1/2(P) Eth1/2(P)

switch (config)#
```

**Step 3.** Examine the MLAG statistics. Run:

```
switch [my-vip: master] (config)# show mlag statistics
IPL 1:
Rx Heartbeat : 516
Tx Heartbeat : 516
Rx IGMP tunnel : 0
Tx IGMP tunnel : 0
RX mlag-notification: 0
TX mlag-notification: 0
Rx port-notification : 0
Tx port-notification : 0
Rx FDB sync : 0
Tx FDB sync : 0
RX LACP manager: 1
TX LACP manager: 0
switch (config)#
```

## 5.3.5 Commands

### protocol mlag

**protocol mlag**  
**no protocol mlag**

Enables MLAG functionality and unhides the MLAG commands.  
 The no form of the command hides the MLAG commands and deletes its database.

| Syntax Description        |                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Role</b>               | admin                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Example</b>            | switch (config) # protocol mlag<br>switch (config) #                                                                                                                                                                                                                                                                                                                              |
| Related Commands          |                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Note</b>               | <ul style="list-style-type: none"> <li>Running the no form of this command hides MLAG commands.</li> <li>MLAG may be enabled without IP routing, but without IP routing an IPL vLAN interface cannot be configured and thus MLAG does not function.</li> <li>MLAG may be enabled without IGMP snooping, but if IGMP snooping is disabled, multi-cast FDBs do not sync.</li> </ul> |

# mlag

|                           |                                                  |
|---------------------------|--------------------------------------------------|
|                           | <b>mlag</b>                                      |
|                           | Enters MLAG configuration mode.                  |
| <b>Syntax Description</b> | N/A                                              |
| <b>Default</b>            | N/A                                              |
| <b>Configuration Mode</b> | Config                                           |
| <b>History</b>            | 3.3.4500                                         |
| <b>Role</b>               | admin                                            |
| <b>Example</b>            | switch (config) # mlag<br>switch (config mlag) # |
| <b>Related Commands</b>   |                                                  |
| <b>Note</b>               |                                                  |

## shutdown

**shutdown**  
**no shutdown**

Enables MLAG.  
The no form of the command disables MLAG.

|                           |                                                              |
|---------------------------|--------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                          |
| <b>Default</b>            | Disabled                                                     |
| <b>Configuration Mode</b> | Config MLAG                                                  |
| <b>History</b>            | 3.3.4500                                                     |
| <b>Role</b>               | admin                                                        |
| <b>Example</b>            | switch (config mlag) # no shutdown<br>switch (config mlag) # |
| <b>Related Commands</b>   |                                                              |
| <b>Note</b>               | This parameter must be similar in all MLAG peers.            |

## interface mlag-port-channel

**interface mlag-port-channel <if-number>**  
**no interface mlag-port-channel <if-number>**

Creates an MLAG interface.  
 The no form of the command deletes the MLAG interface.

|                           |                                                                                                                                                                                                                                                                                       |                                          |

## ipl

**ipl <ipl-id>**  
**no ipl <ipl-id>**

Sets this LAG as an IPL port.  
 The no form of the command resets this LAG as regular LAG.

|                           |                                                                                                                                                                                                                                                                                                                |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• If a LAG is set as IPL, only the commands “[no] shutdown”, “no ipl” and “no interface port-channel” become applicable.</li> <li>• A LAG interface set as IPL must have default LAG configuration, otherwise the set is rejected. Force option can be used.</li> </ul> |

## ipl peer-address

**ipl <ipl-id> peer-address <IP-Address>**

**no ipl <ipl-id>**

Maps a VLAN interface to be used for an IPL LAG and sets the peer IP address of the IPL peer port.

The no form of the command deletes a peer IPL LAG and unbinds this VLAN interface from the IPL function.

## keep-alive-interval

**keep-alive-interval <value>**

**no keep-alive-interval**

Configures the interval during which keep-alive messages are issued between the MLAG switches.

The no form of the command resets this parameter to its default value.

|                           |                                                                                |                                |
|---------------------------|--------------------------------------------------------------------------------|--------------------------------|

| <b>Related Commands</b>   |                                                                                |                                |
| <b>Note</b>               | This parameter must be similar in all MLAG peers.                              |                                |

## mlag-channel-group mode

**mlag-channel-group** <if-number> mode {on | active | passive}  
**no mlag-channel-group**

Binds an Ethernet port to the MLAG LAG.  
 The no form of the command deletes the binding.

## mlag-vip

**mlag-vip** <domain-name> ip [<ip-address> {<masklen> | netmask> [force]]  
**no mlag-vip**

Sets the VIP domain and IP address for MLAG.  
 The no form of the command deletes the VIP domain and IP address.

## reload-delay

**reload-delay <value>**

**no reload-delay**

Specifies the amount of time that MLAG ports are disabled after system reboot. The no form of the command resets this parameter to its default value.

## system-mac

**system-mac** <virtual-mac>  
**no system-mac** <virtual-mac>

Configures virtual system MAC.  
 The no form of the command resets this value to its default value.

| Syntax Description        | virtual-mac                                                                                                                                                            | MAC address |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------|
| <b>Default</b>            | Default is calculated according to the MLAG-VIP name, using the base MAC as VRRP MAC prefix (00:00:5E:00:01:xx) with the suffix hashed from the mlag-vip name 0...255. |             |
| <b>Configuration Mode</b> | Config MLAG                                                                                                                                                            |             |
| <b>History</b>            | 3.4.2000                                                                                                                                                               |             |
| <b>Role</b>               | admin                                                                                                                                                                  |             |
| <b>Example</b>            | switch (config mlag) # system-mac 00:00:5E:00:01:5D<br>switch (config mlag) #                                                                                          |             |
| <b>Related Commands</b>   |                                                                                                                                                                        |             |
| <b>Note</b>               |                                                                                                                                                                        |             |

## upgrade-timeout

**mlag upgrade-timeout <time>**  
**no mlag upgrade-timeout**

Configures the time interval at which the MLAG slave keeps its ports active while in upgrading state.

|                           |                                                                          |                                        |

## 5.4 VLANs

A Virtual Local Area Network (VLAN) is an L2 segment of the network which defines a broadcast domain and is identified by a tag added to all Ethernet frames running within the domain. This tag is called a VLAN ID (VID) and can take a value of 1-4094.

Each port can have a switch mode of either:

- Access – Access port is a port connected to a host. It can accept only untagged frames, and assigns them a default configured VLAN (Port VLAN ID). On egress, traffic sent from the access port is untagged.
- Access-dcb – This mode is Mellanox specific that receives ingress untagged traffic but sends egress priority tag (VLAN ID = 0)
- Hybrid – Hybrid port is a port connected to either switches or hosts. It can receive both tagged and untagged frames and assigns untagged frames a default configured VLAN (Port VLAN ID). It receives tagged frames with VLANs of which the port is a member (these VLANs' names are allowed). On egress, traffic of allowed VLANs sent from the Hybrid port is sent tagged, while traffic sent with PVID is untagged.
- Trunk – Trunk port is a port connecting 2 switches. It accepts only tagged frames with VLANs of which the port is a member. On egress, traffic sent from the Trunk port is tagged. By default, a Trunk port is, automatically, a member on all current VLANs.

### 5.4.1 Configuring Access Mode and Assigning Port VLAN ID (PVID)

➤ *To configure Access mode and assign PVID to interfaces:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a VLAN. Run:

```
switch (config) # vlan 6
switch (config vlan 6) #
```

**Step 4.** Change back to config mode. Run:

```
switch (config vlan 6) # exit
switch (config) #
```

**Step 5.** Enter the interface context. Run:

```
switch (config) # interface ethernet 1/36
switch (config interface ethernet 1/36) #
```

**Step 6.** From within the interface context, configure the interface mode to Access. Run:

```
switch (config interface ethernet 1/36) # switchport mode access
switch (config interface ethernet 1/36) #
```

**Step 7.** From within the interface context, configure the Access VLAN membership. Run:

```
switch (config interface ethernet 1/36) # switchport access vlan 6
switch (config interface ethernet 1/36) #
```

**Step 8.** Change back to config mode. Run:

```
switch (config interface ethernet 1/36) # exit
switch (config) #
```

## 5.4.2 Configuring Hybrid Mode and Assigning Port VLAN ID (PVID)

➤ *To configure Hybrid mode and assign PVID to interfaces:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a VLAN. Run:

```
switch (config) # vlan 6
switch (config vlan 6) #
```

**Step 4.** Change back to config mode. Run:

```
switch (config vlan 6) # exit
switch (config) #
```

**Step 5.** Enter the interface context. Run:

```
switch (config) # interface ethernet 1/36
switch (config interface ethernet 1/36) #
```

**Step 6.** From within the interface context, configure the interface mode to Access. Run:

```
switch (config interface ethernet 1/36) # switchport mode hybrid
switch (config interface ethernet 1/36) #
```

**Step 7.** From within the interface context, configure the Access VLAN membership. Run:

```
switch (config interface ethernet 1/36) # switchport hybrid vlan 6
switch (config interface ethernet 1/36) #
```

**Step 8.** Change to config mode again. Run:

```
switch (config interface ethernet 1/36) # exit
switch (config) #
```

## 5.4.3 Configuring Trunk Mode VLAN Membership

➤ *To configure Trunk mode VLAN membership:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a VLAN. Run:

```
switch (config) # vlan 10
switch (config vlan 10) #
```

**Step 4.** Change back to config mode. Run:

```
switch (config vlan 10) # exit
switch (config) #
```

**Step 5.** Enter the interface context. Run:

```
switch [standalone: master] (config) # interface ethernet 1/35
switch [standalone: master] (config interface ethernet 1/35) #
```

**Step 6.** From within the interface context, configure the interface mode to Trunk. Run:

```
switch [standalone: master] (config interface ethernet 1/35) # switchport mode trunk
switch [standalone: master] (config interface ethernet 1/35) #
```

#### 5.4.4 Configuring Hybrid Mode VLAN Membership

➤ *To configure Hybrid mode VLAN membership:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a VLAN. Run:

```
switch (config) # vlan 10
switch (config vlan 10) #
```

**Step 4.** Change back to config mode. Run:

```
switch (config vlan 10) # exit
switch (config) #
```

**Step 5.** Enter the interface context. Run:

```
switch (config) # interface ethernet 1/35
switch (config interface ethernet 1/35) #
```

**Step 6.** From within the interface context, configure the interface mode to Hybrid. Run:

```
switch (config interface ethernet 1/35) # switchport mode hybrid
switch (config interface ethernet 1/35) #
```

**Step 7.** From within the interface context, configure the allowed VLAN membership. Run:

```
switch (config interface ethernet 1/35) # switchport hybrid allowed-vlan add 10
switch (config interface ethernet 1/35) #
```

**Step 8.** Change to config mode again. Run:

```
switch (config interface ethernet 1/35) # exit
switch (config) #
```

## 5.4.5 Commands

### vlan

**vlan** {<vlan-id> | <vlan-range>}  
**no vlan** {<vlan-id> | <vlan-range>}

Creates a VLAN or range of VLANs, and enters a VLAN context.  
 The no form of the command deletes the VLAN or VLAN range.

| <b>Syntax Description</b> | vlan-id                                                                                                                                                                                                                                                                | 1-4094.                                |      |      |       |   |         |                                        |    |  |

| <b>Note</b>               | Interfaces are not added automatically to VLAN unless configured with trunk or hybrid mode with “all” option turned on.                                                                                                                                                |                                        |      |      |       |   |         |                                        |    |  |

## name

**name** <vlan-name>

**no name**

Adds VLAN name.

The no form of the command deletes the VLAN name.

| <b>Syntax Description</b> | vlan-name                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      | 40-character long string.                                                             |      |      |       |   |         |                                             |     |  |                                                                                       |     |  |                                              |     |  |                                              |     |  |                                              |     |  |                                              |    |              |                       |

## switchport mode

**switchport mode {access | trunk | hybrid | access-dcb}**

**no switchport mode**

Sets the switch port mode.

The no form of the command sets the switch port mode to access.

| Syntax Description | access                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Untagged port. 802.1q tagged traffic are filtered. ## switchport access

**switchport access vlan <vlan-id>**

**no switchport access vlan**

Sets the port access VLAN.

The no form of the command sets the port access VLAN to 1.

| Syntax Description | vlan-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              | 1-4094.                                                                                                                                        |               |      |             |               |        |        |   |  |        |        |   |  |          |        |   |  |          |        |   |  |        |        |   |  |        |        |   |  |        |        |    |  |      |  |  |  |        |        |   |  |

## 5.5 MAC Address Table

### 5.5.1 Configuring Unicast Static MAC Address

You can configure static MAC addresses for unicast traffic. This feature improves security and reduces unknown unicast flooding.

➤ **To configure Unicast Static MAC address:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Run the command `mac-address-table static unicast <destination mac address> vlan <vlan identifier(1-4094)> interface ethernet <slot>/ <port>`.

```
switch (config) # mac-address-table static unicast 00:11:22:33:44:55 vlan 1 interface
ethernet 0/1
```

### 5.5.2 MAC Learning Considerations

MAC learning may be disabled using the command `mac-learning disable` which is beneficial in the following situations:

- To prevent denial-of-service attacks
- To manage the available MAC address table space by controlling which interfaces can learn MAC addresses
- To duplicate to a dedicated server (port7) all the packets that one host (host1; port1) sends to another (host2; port2), like in port mirroring. To accomplish this, MAC learning is disabled on port2. In this case the FDB does not obtain the MAC address of host2. Also, to prevent broadcast to every port, it is possible to configure a VLAN (VLAN 80) which ports 1, 2 and 7 are member of.

**Figure 20: MAC Learning Disable Example Case**

### 5.5.3 Commands

#### mac-address-table aging-time

**mac-address-table aging-time <age>**  
**no mac-address-table aging-time**

Sets the maximum age of a dynamically learnt entry in the MAC address table.  
 The no form of the command resets the aging time of the MAC address table to its default.

## mac-address-table static

**mac-address-table static** <mac address> vlan <vlan> interface <if-type> <if-number>

**no mac-address-table static** <mac address> vlan <vlan> interface <if-type> <if-number>

Configures a static MAC address in the forwarding database.

The no form of the command deletes a configured static MAC address from the forwarding database.

| <b>Related Commands</b>   | <pre>show mac-address-table mac-address-table aging time</pre>                                                                                                                                                                                                                                                                                                 |                                          |
| <b>Note</b>               | The no form of the command will not clear a dynamic MAC address. Dynamic MAC addresses are cleared using the “clear mac-address-table dynamic” command.                                                                                                                                                                                                        |                                          |

## mac-learning disable

**mac-learning disable**  
**no mac-learning disable**

Disables MAC-address learning.  
 The no form of the command enables MAC-address learning.

## 5.6 Spanning Tree

The operation of Rapid Spanning Tree Protocol (RSTP) provides for rapid recovery of connectivity following the failure of a bridge/bridge port or a LAN. The RSTP component avoids this delay by calculating an alternate root port, and immediately switching over to the alternate port if the root port becomes unavailable. Thus, using RSTP, the switch immediately brings the alternate port to forwarding state, without the delays caused by the listening and learning states. The RSTP component conforms to IEEE standard 802.1D 2004.

RSTP enhancements is a set of functions added to increase the volume of RSTP in Mellanox switches. It adds a set of capabilities related to the behavior of ports in different segments of the network. For example: the required behavior of a port connected to a non-switch entity, such as host, is to converge quickly, while the required behavior of a port connected to a switch entity is to converge based on the RSTP parameters.

Additionally, it adds security issues on a port and switch basis, allowing the operator to determine the state and role of a port or the entire switch should an abnormal event occur. For example: If a port is configured to be root-guard, the operator will not allow it to become a root-port under any circumstances, regardless of any BPDUs that will have been received on the port.

### 5.6.1 Port Priority and Cost

When two ports on a switch are part of a loop, the STP port priority and port path cost configuration determine which port on the switch is put in the forwarding state and which port is put in the blocking state.

To configure port priority use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree port-priority <0-240>
```

To configure port path cost use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree cost <1-2000000000>
```

### 5.6.2 Port Type

Port type has the following configuration options:

- **edge** – is not assumed to be converged by the RSTP learning/forwarding mechanism. It converges to forwarding quickly.

It is recommended to configure the port type for all ports connected to hosts as edge ports.

- **normal** – is assumed to be connected to a switch, thus it tries to be converged by the RSTP learning/forwarding. However, if it does not receive any BPDUs, it is operationally moved to be edge.
- **network** – is assumed to be connected to a switch. If it does not receive any BPDUs, it is moved to discarding state.

Each of these configuration options is mutually exclusive.

Port type is configured using the command `spanning-tree port type`. It may be applied globally on the switch (Config) level, which configures all switch interfaces. Another option is to configure ports individually by entering the interface's configuration mode.

- Global configuration:

```
switch (config)# spanning-tree port type {edge , normal , network} default
```

- Interface configuration:

```
switch (config interface ethernet <inf>)# spanning-tree port type {edge , normal, network}
```

### 5.6.3 BPDU Filter

Using BPDU filter prevents the CPU from sending/receiving BPDUs on specific ports.

BPDU filtering is configured per interface. When configured, the port does not send any BPDUs and drops all BPDUs that it receives. To configure BPDU filter, use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree bpdufilter {enable , disable}
```

Configuring BPDU filtering on a port connected to a switch can cause bridging loops because the port filters any BPDU it receives and goes to forwarding state.

### 5.6.4 BPDU Guard

BPDU guard is a security feature which, when enabled, shuts down the port in case it receives BPDU packets. This feature becomes useful when connecting to an unauthorized switch.

To configure BPDU guard use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree port type <type> bpduguard
```

### 5.6.5 Loop Guard

Loop guard is a feature that prevents loops in the network.

When a blocking port in a redundant topology transitions to the forwarding state (accidentally), an STP loop occurs. This happens when BPDUs are no longer received by one of the ports in a physically redundant topology.

Loop guard is useful in switched networks where devices are connected point-to-point. A designated bridge cannot disappear unless it sends an inferior BPDU or brings the link down on a point-to-point connection.

The loop guard configuration is only allowed on “network” port type.

If loop guard is enabled and the port does not receive BPDUs, the port is put into an inconsistent state (blocking) until the port starts to receive BPDUs again. A port in the inconsistent state does not transmit BPDUs. If BPDUs are received again, loop guard alters its inconsistent state condition. STP converges to a stable topology without the failed link or bridge after loop guard isolates the failure.

Disabling loop guard moves all loop-inconsistent ports to listening state.

To configure loop guard use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree guard loop
```

## 5.6.6 Root Guard

Configuring root guard on a port prevents that port from becoming a root port. A port put in root-inconsistent (blocked) state if an STP convergence is triggered by a BPDU that makes that port a root port. The port is unblocked after the port stops sending BPDUs.

To configure loop guard use the following command:

```
switch (config interface ethernet <inf>)# spanning-tree guard root
```

## 5.6.7 MSTP

Spanning Tree Protocol (STP) is a mandatory protocol to run on L2 Ethernet networks to eliminate network loops and the resulting broadcast storm caused by these loops. Multiple STP (MSTP) enables the virtualization of the L2 domain into several VLANs, each governed by a separate instance of a spanning tree which results in a network with higher utilization of physical links while still keeping the loop free topology on a logical level.

Up to 64 MSTP instances can be defined in the switch. Up to 64 VLANs can be mapped to a single MSTP instance. MSTP instance 0 (the default instance) may have all possible VLANs (1-4094) mapped to it.

For MSTP network design over Mellanox L2 VMS, please refer to [Mellanox Virtual Modular Switch Reference Guide](#).

## 5.6.8 RPVST

Rapid Per-VLAN Spanning Tree (RPVST) flavor of the STP provides finer-grained traffic by paving a spanning-tree instance per each configured VLAN. Like MSTP, it allows a better utilization of the network links comparing to RSTP.

Figure 21 exhibits a typical RPVST network configuration to get a better utilization on the inter-switch trunk ports.

**Figure 21: RPVST Network Config**

### 5.6.8.1 RPVST and VLAN Limitations

When the STP of the switch is set to RPVST, spanning tree is set on each of the configured VLANs in the system by default. To enable the spanning tree mode, the command “spanning-tree” must be run.

Each VLAN runs an STP state machine and an RPVST instance. There is a global limitation on the number of active state machines that can operate in MLNX-OS. Enforcement of this limitation is done through the maximum number of VLANs allowed in the system. On x86 switch systems the limitation is 128 VLANs and on PPC systems it ranges from 13-18 VLANs depending on the switch system. The more ports the switch system has the less VLANs it can support.

**Table 51 - Supported VLANs by RPVST per Switch System**

| Switch System Model | Number of Supported VLANs |
|---------------------|---------------------------|
| x86 systems         | 128                       |
| SX1012              | 17                        |
| SX1016              | 13                        |
| SX1024              | 13                        |
| SX1035              | 13                        |
| SX1036              | 13                        |

The state machine takes attributes like forward time, hello time, max age and priority, etc.

When configuring priority on a VLAN in RPVST, the operational priority given to the VLAN is a summation of what the user configured and the value of the VLAN itself. For example running “spanning-tree vlan 10 priority 32768” yields a priority of 32778 for VLAN 10.

### 5.6.8.2 RPVST and RSTP Interoperability

**Figure 22: RPVST and RSTP Cluster**

RPVST domains can be interconnected by a standard 802.1Q domain that runs RSTP protocol. While the RSTP domain builds a single common instance spanning tree, the RPVST domains at the edge continue to build a tree per VLAN while exchanging tagged RPVST multicast BPDUs.

(This exchange may happen on untagged RPVST BPDUs as well.) The switch devices that are in the boundary between the RPVST and the RSTP domains should be configured as RPVST mode.

When set to RPVST mode, the switch continues to run the common instance spanning tree (CIST) state machine on VLAN 1 by exchanging IEEE BPDUs with the legacy RSTP switches.

To successfully connect RSTP and RPVST domains, the system administrator must align the native VLAN configuration across all network switches, or in other words, the internal identification of untagged packets to VLAN.

## 5.6.9 Commands

### spanning-tree

**spanning-tree**  
**no spanning-tree**

Globally enables the spanning tree feature.  
The no form disables the spanning tree feature.

|                           |                                                         |
|---------------------------|---------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                     |
| <b>Default</b>            | Spanning tree is enabled.                               |
| <b>Configuration Mode</b> | Config                                                  |
| <b>History</b>            | 3.1.0000                                                |
| <b>Role</b>               | admin                                                   |
| <b>Example</b>            | switch (config) # no spanning-tree<br>switch (config) # |
| <b>Related Commands</b>   | show spanning-tree                                      |
| <b>Note</b>               |                                                         |

## spanning-tree mode

**spanning-tree mode {rst | mst | rpvst}**

**no spanning-tree mode**

Changes the spanning tree mode.

The no form of the command sets the parameter to its default value.

|                           |                                                                                                                                                                                                                  |                               |

## spanning-tree (timers)

**spanning-tree** [**forward-time** <time in secs> | **hello-time** <time in secs> | **max-age** <time in secs>]

**no spanning-tree** [**forward-time** | **hello-time** | **max-age** | **priority**]

Sets the spanning tree timers.

The no form of the command sets the timer to default.

## spanning-tree port type (default global)

**spanning-tree port type {edge [bpdufilter | bpduguard] | network [bpduguard] | normal [bpduguard]} default**  
**no spanning-tree port type default**

Configures all switch interfaces as edge/network/normal ports. These ports can be connected to any type of device.

The no form of the command disables the spanning tree operation.

## spanning-tree priority

**spanning-tree priority <bridge-priority>**

**no spanning-tree priority**

Sets the spanning tree bridge priority.

The no form of the command sets the bridge priority to default.

## spanning-tree port-priority

**spanning-tree port-priority <priority>**

**no spanning-tree port-priority**

Configures the spanning-tree interface priority.

The no form of the command returns configuration to its default.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>LAG default cost is calculated by dividing the port speed by the number of active links in UP state. For example: if there were 4 links in the LAG out of which only two are in UP state, assuming the port speed is 10Gbps, the LAG cost will be <math>2000/2 = 1000</math>.</li> <li>When configuring the cost for a LAG, the cost will be fixed to this configuration, no matter what the number of active links (UIP state) in the LAG is</li> <li>Unstable network may cause the LAG cost to change dynamically assuming the cost parameter is not configured for anything else other than default</li> </ul> |                                                                              |

## spanning-tree port type

**spanning-tree port type <port type>**  
**no spanning-tree port type**

Configures spanning-tree port type  
 The no form of the command returns configuration to default.

## spanning-tree guard

**spanning-tree guard {loop | root}**  
**no spanning-tree guard {loop | root}**

Configures spanning-tree guard.  
 The no form of the command returns configuration to default.

|                           |                                                                                                                                                           |                                                                                                                                                                                              |

## spanning-tree bpdudfilter

**spanning-tree bpdudfilter {disable | enable}**

**no spanning-tree bpdudfilter**

Configures spanning-tree BPDU filter on the interface. The interface will ignore any BPDU that it receives and will not send PDUs, The STP state on the port will move to the forwarding state.

The no form of the command returns the configuration to default.

## spanning-tree mst max-hops

**spanning-tree mst max-hops <max-hops>**

**no spanning-tree mst max-hops**

Specifies the max hop value inserts into BPDUs that sent out as the root bridge.  
The no form of the command sets the parameter to its default value.

## spanning-tree mst priority

**spanning-tree mst <mst-instance> priority <priority>**

**no spanning-tree mst <mst-instance> priority**

Configures the specified instance's priority number.

The no form of the command sets the parameter to its default value.

## spanning-tree mst vlan

**spanning-tree mst <mst-instance> vlan <vlan-range>**  
**no spanning-tree mst <mst-instance> vlan <vlan-range>**

Maps a VLAN or a range of VLANs into an MSTP instance.  
 The no form of the command unmaps a VLAN or a range of VLANs from MSTP instances.

| <b>Role</b>               | admin                                                               |                                                                                   |
| <b>Example</b>            | switch (config)# spanning-tree mst 1 vlan 10-20<br>switch (config)# |                                                                                   |
| <b>Related Commands</b>   |                                                                     |                                                                                   |
| <b>Note</b>               | This command is available when global STP mode is set to MST        |                                                                                   |

## spanning-tree mst revision

**spanning-tree mst revision <number>**

**no spanning-tree mst revision**

Configures the MSTP revision number.

The no form of the command sets the parameter to its default value.

|                           |                                                                                                                                                                                                                                                                 |                                            |

## spanning-tree mst name

**spanning-tree mst name <name>**

**no spanning-tree mst name**

Configures the MSTP name.

The no form of the command sets the parameter to its default value.

## spanning-tree mst root

**spanning-tree mst <mst-instance> root <role>**

**no spanning-tree mst <mst-instance> root**

Changes the bridge priority for the specified MST instance to the following values:

- Primary – 8192
- Secondary – 16384

The no form of the command sets the parameter to its default value.

| Note               | <ul style="list-style-type: none"><li>• The root command is a way to automate a system configuration while ‘playing’ with the priority field. The priority field granularity may be too explicit for some users in case you wish to have 2 levels of priority (primary and secondary). So by default all the switches get the same priority and while using the root option you can get the role of master and backup by setting the priority field to a predefined value.</li><li>• This command is available when global STP mode is set to MST.</li></ul> |                                        |

## spanning-tree mst port-priority

**spanning-tree mst {mst-instance} port-priority <priority>**

**no spanning-tree mode**

Changes the spanning tree mode.

The no form of the command sets the parameter to its default value.

## spanning-tree mst cost

**spanning-tree mst {mst-instance} cost <cost-value>**  
**no spanning-tree mode**

Configures the cost per MSTP instance.  
 The no form of the command sets the parameter to its default value.

## spanning-tree vlan forward-time

**spanning-tree vlan <vid> forward-time <secs>**

**no spanning-tree vlan <vid> forward-time**

Configures how fast an interface changes its spanning tree state from Blocking to Forwarding.

The no form of the command resets the parameter value to its default.

## spanning-tree vlan hello-time

**spanning-tree vlan <vid> hello-time <secs>**

**no spanning-tree vlan <vid> hello-time**

Configures how often the switch broadcasts its hello message to other switches when it is the root of the spanning tree.

The no form of the command resets the parameter value to its default.

## spanning-tree vlan max-age

**spanning-tree vlan <vid> max-age <secs>**

**no spanning-tree vlan <vid> max-age**

Sets the maximum age allowed for the Spanning Tree Protocol information learned from the network on any port before it is discarded.

The no form of the command resets the parameter value to its default.

## spanning-tree vlan priority

**spanning-tree vlan <vid> priority <priority>**

**no spanning-tree vlan <vid> priority**

Configures RPVST instance port priority.

The no form of the command resets the parameter value to its default.

## show spanning-tree

### show spanning-tree

Displays spanning tree information.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## show spanning-tree interface

**show spanning-tree interface {ethernet <slot>/<port> | port-channel <port-channel> | mlag-port-channel <mlag-port-channel>}**

Display running state for specific interfaces.

## show spanning-tree root

### show spanning-tree root

Displays root multi-spanning-tree information.

| Syntax Description | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |                   |           |            |         |         |           |  |          |          |          |           |            |         |         |           |       |       |       |       |       |       |       |       |      |       |                   |     |   |    |    |         |      |       |                   |   |   |    |    |   |      |   |                   |   |   |    |    |   |      |       |                   |   |   |    |    |   |

## 5.7 OpenFlow

MLNX-OS supports OpenFlow 1.0. OpenFlow is a network protocol that facilitates direct communication between network systems via Ethernet. Software Defined Networks (SDN) allows a centralist management of network equipment. OpenFlow allows the SDN controller to manage SDN equipment. The OpenFlow protocol allows communication between the OpenFlow controller and OpenFlow agent.

OpenFlow is useful to manage switches and allow applications running on the OpenFlow controller to have access to the switch's datapath and provide functionality such as flow steering, security enhancement, traffic monitoring and more.

The OpenFlow controller communicates with the OpenFlow switch over secured channel using OpenFlow protocol.

An OpenFlow switch contains a flow table which contains flows inserted by the OpenFlow controller. And the OpenFlow switch performs packet lookup and forwarding according to those rules.

Mellanox OpenFlow switch implementation is based on the hybrid model, allowing the coexistence of an OpenFlow pipeline and a normal pipeline. In this model, a packet is forwarded according to OpenFlow configuration, if such configuration is matched with the packet parameters. Otherwise, the packet is handled by the normal (regular forwarding/routing) pipeline.

The OpenFlow specification defines:

“OpenFlow-hybrid switches support both OpenFlow operation and normal Ethernet switching operation, i.e. traditional L2 Ethernet switching, VLAN isolation, L3 routing (IPv4 routing, IPv6 routing...), ACL and QoS processing. Those switches must provide a classification mechanism outside of OpenFlow that routes traffic to either the OpenFlow pipeline or the normal pipeline. For example, a switch may use the VLAN tag or input port of the packet to decide whether to process the packet using one pipeline or the other, or it may direct all packets to the OpenFlow pipeline.”

Utilizing the built-in capabilities of the hybrid switch/router is the main benefit of the hybrid mode. It increases network performance and efficiency – faster processing of new flows as well as lower load on the controllers. The hybrid switch processes non-OpenFlow data through its local management plane and achieve better efficiency and use of resources, compared to the pure OpenFlow switch.

### 5.7.1 Flow Table

The flow table contains flows which are used to perform packet lookup, modification and forwarding. Each flow has a 12 tuple key. The key is used in order to classify a packet into a certain flow. The key contains the flowing fields: ingress port, source MAC, destination MAC, Ether-Type, VLAN ID, PCP, source IP, destination IP, IP protocol, IP ToS bits, TCP/UDP source port and TCP/UDP destination port.

The flow key can have a specific value for each field or wildcard which signals to the switch to ignore this part of the key.

Each packet passes through the flow table once a match is found; the switch performs the actions configured to the specific flow by the OpenFlow controller.

Upkeeping a flow table enables the switch to forward incoming traffic with a simple lookup on its flow table entries. OpenFlow switches perform a check for matching entries on, or ignore using a wildcard, specific fields of the ingress traffic. If the entry exists, the switch performs the action associated with that flow entry. Packets without a flow entry match are forwarded according to the normal pipeline (hybrid switch).

Every flow entry contains one of the following parameters:

1. Header fields for matching purposes with each entry containing a specific value or a wildcard which could match all entries.
2. Matching packet counters which are useful for statistical purposes, in order to keep track of the number of packets.
3. Actions which specify the manner in which to handle the packets of a flow which can be any of the following:
  - a. Forwarding the packet
  - b. Dropping the packet
  - c. Forwarding the packet to the OpenFlow controller
  - d. Modifying the VLAN, VLAN priority (PCP), and/or stripping the VLAN header

The flow table supports up to 1000 flows.

## 5.7.2 Configuring OpenFlow

### ➤ *To run OpenFlow on a switch:*

**Step 1.** Unlock the OpenFlow CLI commands. Run:

```
switch (config) # protocol openflow
```

**Step 2.** Configure interfaces to be managed by OpenFlow. Run:

```
switch (config) # interface ethernet 1/1-1/4 openflow mode hybrid
```

**Step 3.** Configure the OpenFlow controller IP and TCP port. Run:

```
switch (config) # openflow controller-ip 10.209.0.205 tcp-port 6633
```

**Step 4.** (Optional) Verify the OpenFlow configuration. Run:

```
switch (config) # show openflow
OpenFlow version: OF VERSION 1.0
Table size: 1000, 0 in use
Active controller ip: 10.209.0.205 port: 6633
Connection status: HANDSHAKE_COMPLETE (CONNECTED)
Forward-to-controller: ospf lldp arp-unicast arp-broadcast (all)
Enabled ports: Eth1/1 Eth1/2 Eth1/3 Eth1/4
switch (config) #
```

To be able to configure the switch using the controller, you should see the following line in the output:

Connection status must be: HANDSHAKE\_COMPLETE (CONNECTED).

## 5.7.3 Commands

### protocol openflow

**protocol openflow**  
**no protocol openflow**

Unhides the OpenFlow commands.  
The no form of the command hides the OpenFlow commands.

## openflow mode hybrid

**openflow mode hybrid**  
**no openflow mode**

Enables OpenFlow on the port.  
The no form of the command returns the port to its default state.

## controller-ip

**controller-ip <ip-address> [tcp-port <port-number>]**

**no controller-ip <ip-address> tcp-port**

Sets the OpenFlow controller's IP & TCP port.

The no form of the command sets the parameter to its default.

## datapath-id

**datapath-id <value>**

**no datapath-id**

Sets a specific identifier for the switch with which the controller is communicating. The no form of the command resets the parameter to its default value.

## forward-to-controller

**forward-to-controller** {[ospf] [lldp] [arp-unicast] [arp-broadcast] all | none}

Forwards the selected traffic types to the controller from all the ports on which OpenFlow enabled.

|                           |                                                                                            |                                                   |

## 5.8 IGMP Snooping

Only IGMP Snooping v1 and v2 are supported.

The Internet Group Multicast Protocol (IGMP) is a communications protocol used by hosts and adjacent routers on IP networks to establish multicast group memberships. The host joins a multicast-group by sending a join request message towards the network router, and responds to queries sent from the network router by dispatching a join report.

A given port can be either manually configured to be a router-port or it can be dynamically manifested when having received a query, hence, the network router is connected to this port. All IGMP Snooping Control packets received from hosts (joins/leaves) are forwarded to the router-port, and the router-port updates its multicast-group data-base accordingly. Each dynamically learnt multicast group will be added to all of the router-ports on the switch.

As many as 5K multicast groups can be created on the switch.

### 5.8.1 Configuring IGMP Snooping

You can configure IGMP snooping to establish multicast group memberships.

➤ **To configure IGMP snooping:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable IGMP snooping globally. Run:

```
switch (config) # ip igmp snooping
switch (config) #
```

**Step 4.** Enable IGMP snooping on a VLAN. Run:

```
switch (config) # vlan 2
switch (config vlan 2) # ip igmp snooping
```

### 5.8.2 Defining a Multicast Router Port on a VLAN

You can define a Multicast Router (MRouter) port on a VLAN in one of the following methods:

➤ **To change the interface switchport to trunk:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable IGMP snooping globally. Run:

```
switch (config) # ip igmp snooping
switch (config) #
```

- Step 4.** Change the interface switchport mode of the port (the interface is member of VLAN 1 by default). Run:

```
switch (config) # interface ethernet 1/1
switch (config interface ethernet 1/1) # switchport mode trunk
```

- Step 5.** Change back to config mode. Run:

```
switch (config interface ethernet 1/1) # exit
switch (config) #
```

- Step 6.** Define the MRouter port on the VLAN. Run:

```
switch (config) # vlan 2
switch (config vlan 2) # ip igmp snooping mrouter interface ethernet 1/1
switch (config vlan 2) #
```

➤ **To change the interface switchport to hybrid:**

- Step 1.** Log in as admin.

- Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

- Step 3.** Enable IGMP snooping globally. Run:

```
switch (config) # ip igmp snooping
switch (config) #
```

- Step 4.** Create a VLAN. Run:

```
switch (config) # vlan 200
switch (config vlan 200) #
```

- Step 5.** Change back to config mode. Run:

```
switch (config vlan 200) # exit
switch (config) #
```

- Step 6.** Change the interface switchport mode of the port (the interface is member of VLAN 1 by default). Run:

```
switch (config) # interface ethernet 1/36
switch (config interface ethernet 1/36) # switchport mode hybrid
```

- Step 7.** Attach the VLAN to the port's interface. Run:

```
switch (config interface ethernet 1/36) # switchport mode hybrid allowed-vlan 200
switch (config interface ethernet 1/36) #
```

- Step 8.** Change to config mode again. Run:

```
switch (config interface ethernet 1/36) # exit
switch (config) #
```

- Step 9.** Define the MRouter port on the VLAN. Run:

```
switch (config) # vlan 200
switch (config vlan 200) # ip igmp mrouter interface ethernet 1/36
switch (config vlan 200) #
```

### 5.8.3 IGMP Snooping Querier

IGMP Snooping Querier compliments the IGMP snooping functionality. IGMP Snooping Querier is used to support IGMP snooping in a VLAN where PIM and IGMP are not configured because the multicast traffic does not need to be routed. When IGMP Snooping Querier is enabled, IGMP queries are sent out periodically by the switch through all ports in the VLAN and to which hosts wishing to receive IP multicast traffic respond with IGMP report messages. IGMP Snooping Querier must be used in conjunction with IGMP snooping as IGMP snooping listens to these IGMP reports to establish appropriate forwarding.

➤ **To configure IGMP Snooping Querier:**

**Step 1.** Enable the IGMP snooping on the switch. Run:

```
switch (config) # ip igmp snooping
```

**Step 2.** Enable the IGMP snooping querier on a specific VLAN. Run:

```
switch (config) # vlan 10
switch (config vlan 10)# ip igmp snooping querier
```

**Step 3.** Set the query interval time. Run:

```
switch (config vlan 10)# igmp snooping querier query-interval 25
```

**Step 4.** (Optional) Verify the IGMP snooping querier configuration. Run:

```
switch (config vlan 10)# show ip igmp snooping querier
VLAN 10 IGMP Querier Present query-interval: 125 address: 1.1.1.2 version: 2
switch (config vlan 10)#
```

## 5.8.4 Commands

### ip igmp snooping (admin)

**ip igmp snooping**  
**no ip igmp snooping**

Enables IGMP snooping globally or per VLAN.  
 The no form of the command disables IGMP snooping globally or per VLAN.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Note</b>               | IGMP snooping has global admin state, and per VLAN admin state. Both states need to be enabled in order to enable the IGMP snooping on a specific VLAN.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## ip igmp snooping (config)

**ip igmp snooping {last-member-query-interval <1-25> | proxy reporting mrouter-timeout <60-600> | port-purge-timeout <130-1225> | report-suppression-interval <1-25>}**

**no ip igmp snooping {last-member-query-interval | proxy reporting | mrouter-timeout | report-suppression-interval}**

Configures IGMP global parameters.

The no form of the command resets the IGMP global parameters to default.

**Example**

```
switch (config) # ip igmp snooping report-suppression-interval 3
switch (config) # show ip igmp snooping
```

IGMP snooping global configuration:

```
IGMP snooping globally enabled
IGMP snooping operationally enabled
Proxy-reporting globally disabled
Last member query interval is 1 seconds
Mrouter timeout is 125 seconds
Port purge timeout is 260 seconds
Report suppression interval is 3 seconds
```

```
switch (config) #
```

**Related Commands**

```
ip igmp snooping (admin)
show ip igmp snooping
```

**Note**

## ip igmp snooping fast-leave

**ip igmp snooping fast-leave**  
**no ip igmp snooping fast-leave**

Enables fast leave processing on a specific interface.  
 The no form of the command disables fast leave processing on a specific interface.

## ip igmp snooping static-group

**ip igmp snooping static-group** <IP address> interface <type> <number>  
**no ip igmp snooping static-group** <IP address> interface <type> <number>

Creates a static multicast group and attaches a port to a specified group.  
 The no form of the command deletes the interface from the multicast group.

| Example            | <pre>switch (config)# vlan 1 switch (config vlan 1) # ip igmp snooping static-group 230.0.0.1 interface ethernet 1/1 switch (config vlan 1) # show ip igmp snooping groups Vlan ID      Group          St/Dyn    Ports ----- 1            230.0.0.1          St        Eth1/1 Total Num of Dynamic Group Addresses 0 Total Num of Static Group Addresses 1 switch (config vlan 1) #</pre> |                                                                              |  |
| Related Commands   | show ip igmp snooping groups                                                                                                                                                                                                                                                                                                                                                              |                                                                              |  |
| Note               | If the deleted interface is the last port, it deletes the entire multicast group.                                                                                                                                                                                                                                                                                                         |                                                                              |  |

## ip igmp snooping mrouter

**ip igmp snooping mrouter interface <type> <number>**  
**no ip igmp snooping mrouter interface <type> <number>**

Creates a static multicast router port on a specific VLAN, on a specific interface.  
 The no form of the command removes the static multicast router port from a specific VLAN.

| <b>Role</b>               | admin                                                                                                                                                                                                                                               |
| <b>Example</b>            | <pre>switch (config)# vlan 1 switch (config vlan 1) # ip igmp snooping mrouter interface ethernet 1/1 switch (config vlan 1) # show ip igmp snooping mrouter Vlan          Ports ----- 1              Eth1/1(static) switch (config vlan 1) #</pre> |
| <b>Related Commands</b>   | show ip igmp snooping mrouter                                                                                                                                                                                                                       |
| <b>Note</b>               | The multicast router port can be created only if IGMP snooping is enabled both globally and on the VLAN.                                                                                                                                            |

## ip igmp snooping unregistered multicast

**ip igmp snooping unregistered multicast <options>**

**no ip igmp snooping unregistered multicast**

Sets the behavior of the snooping switch for unregistered multicast traffic.  
The no form of the command sets it default.

## 5.9 Link Layer Discovery Protocol (LLDP)

The Link Layer Discovery Protocol (LLDP) is a vendor-neutral Link Layer protocol in the Internet Protocol Suite used by network devices for advertising their identity, capabilities, and neighbors on a IEEE 802 LAN. The protocol is formally defined in IEEE 802.1AB.

### 5.9.1 Configuring LLDP

➤ *To configure the LLDP on the switch:*

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable LLDP globally on the switch. Run:

```
switch (config) # lldp
switch (config) #
```

**Step 4.** Enable LLDP per interface. Run:

```
switch (config interface ethernet 1/1) # lldp receive
switch (config interface ethernet 1/1) # lldp transmit
```

**Step 5.** Show LLDP local information. Run:

```
switch (config) # show lldp local

LLDP is Enabled

Chassis id: 00:11:22:33:44:55
System Name: "switch-111111"
System Description: my-system-description
Supported capabilities: B
Supported capabilities enabled: B
```

**Step 6.** Show LLDP remote information. Run:

```
switch (config)# show lldp interfaces ethernet 1/1 remote

Ethernet 1/1
Remote Index: 1
Remote chassis id: 00:11:22:33:44:55 ; chassis id subtype: mac
Remote port-id: ethernet 1/2; port id subtype: local
Remote port description: ethernet 1/2
Remote system name: remote-system
Remote system description: remote-system-description
Remote system capabilities supported: B ; B
```

### 5.9.2 DCBX

Data Center Bridging (DCB) is an enabler for running the Ethernet network with lossless connectivity using priority-based flow control and enhanced transmission selection. DCBx (exchange)

compliments the DCB implementation by offering a dynamic protocol that communicates DCB attributes between peering endpoint.

## 5.9.3 Commands

### lldp

**lldp**  
**no lldp**

Enables LLDP globally.  
The no form of the command disables the LLDP.

|                           |                                           |
|---------------------------|-------------------------------------------|
| <b>Syntax Description</b> | N/A                                       |
| <b>Default</b>            | Disabled                                  |
| <b>Configuration Mode</b> | Config                                    |
| <b>History</b>            | 3.2.0300                                  |
| <b>Role</b>               | admin                                     |
| <b>Example</b>            | switch (config)# lldp<br>switch (config)# |
| <b>Related Commands</b>   | show lldp local                           |
| <b>Note</b>               |                                           |

## lldp reinit

**lldp reinit <seconds>**  
**no lldp reinit**

Sets the delay in seconds from enabling the LLDP on the port until re-initialization will be attempted.  
 The no form of the command sets the parameter to default.

|                           |                                                     |      |
|---------------------------|-----------------------------------------------------|------|
| <b>Syntax Description</b> | seconds                                             | 1-10 |
| <b>Default</b>            | 2                                                   |      |
| <b>Configuration Mode</b> | Config                                              |      |
| <b>History</b>            | 3.2.0300                                            |      |
| <b>Role</b>               | admin                                               |      |
| <b>Example</b>            | switch (config)# lldp reinit 10<br>switch (config)# |      |
| <b>Related Commands</b>   | show lldp timers                                    |      |
| <b>Note</b>               |                                                     |      |

## lldp timer

**lldp timer <seconds>**  
**no lldp timer**

Sets the LLDP interval at which LLDP frames are transmitted. (lldpMessageTxInterval)  
 The no form of the command sets the parameter to default.

|                           |                                                    |         |
|---------------------------|----------------------------------------------------|---------|
| <b>Syntax Description</b> | seconds                                            | 5-32768 |
| <b>Default</b>            | 30                                                 |         |
| <b>Configuration Mode</b> | Config                                             |         |
| <b>History</b>            | 3.2.0300                                           |         |
| <b>Role</b>               | admin                                              |         |
| <b>Example</b>            | switch (config)# lldp timer 10<br>switch (config)# |         |
| <b>Related Commands</b>   | show lldp timers                                   |         |
| <b>Note</b>               |                                                    |         |

## lldp tx-delay

**lldp tx-delay <seconds>**

**no lldp tx-delay**

Indicates the delay in seconds between successive LLDP frame transmissions  
The no form of the command sets the parameter to default.

|                           |                                                                                                                                          |        |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>Syntax Description</b> | seconds                                                                                                                                  | 1-8192 |
| <b>Default</b>            | 2                                                                                                                                        |        |
| <b>Configuration Mode</b> | Config                                                                                                                                   |        |
| <b>History</b>            | 3.2.0300                                                                                                                                 |        |
| <b>Role</b>               | admin                                                                                                                                    |        |
| <b>Example</b>            | switch (config)# lldp tx-delay 10<br>switch (config)#                                                                                    |        |
| <b>Related Commands</b>   | show lldp timers                                                                                                                         |        |
| <b>Note</b>               | The recommended value for the tx-delay is set by the following formula:<br>$1 \leq \text{lldp tx-delay} \leq (0.25 * \text{lldp timer})$ |        |

## lldp tx-hold-multiplier

**lldp tx-hold-multiplier <seconds>**

**no lldp tx-hold-multiplier**

The time-to-live value expressed as a multiple of the lldpMessageTxInterval object. The no form of the command sets the parameter to default.

|                           |                                                                                                                                                                                                                                                                                                                                                                |        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>Syntax Description</b> | seconds                                                                                                                                                                                                                                                                                                                                                        | 1-8192 |
| <b>Default</b>            | 2                                                                                                                                                                                                                                                                                                                                                              |        |
| <b>Configuration Mode</b> | Config                                                                                                                                                                                                                                                                                                                                                         |        |
| <b>History</b>            | 3.2.0300                                                                                                                                                                                                                                                                                                                                                       |        |
| <b>Role</b>               | admin                                                                                                                                                                                                                                                                                                                                                          |        |
| <b>Example</b>            | switch (config)# lldp tx-hold-multiplier 10<br>switch (config)#                                                                                                                                                                                                                                                                                                |        |
| <b>Related Commands</b>   | show lldp timers                                                                                                                                                                                                                                                                                                                                               |        |
| <b>Note</b>               | The actual time-to-live value used in LLDP frames, can be expressed by the following formula: $TTL = \min(65535, (lldpMessageTxInterval * lldpMessageTxHoldMultiplier))$ For example, if the value of lldpMessageTxInterval is '30', and the value of lldpMessageTxHoldMultiplier is '4', then the value '120' is encoded in the TTL field in the LLDP header. |        |

## lldp {receive | transmit}

**lldp {receive | transmit}**  
**no lldp {receive | transmit}**

Enables LLDP to be received or transmitted on this port.  
 The no form of the command disables the LLDP to be received or transmitted on this port.

|                           |                                                                                                                                                          |

## 5.10 Quality of Service (QoS)

### 5.10.1 Priority Flow Control and Link Level Flow Control

Priority Flow Control (PFC) provides an enhancement to the existing pause mechanism in Ethernet. The current Ethernet pause option stops all traffic on a link. PFC creates eight separate virtual links on the physical link and allows any of these links to be paused and restarted independently, enabling the network to create a no-drop class of service for an individual virtual link. PFC has 8 possible priorities (3 bits in VLAN header). Each priority can be mapped to one of 4 possible queues in the ingress.

The PFC software offers the following features:

- Provides per-priority enabling or disabling of flow control
- Transmits PFC-PAUSE frames when the receive threshold for a particular traffic class is reached
- Provides the management capability for an administrator to configure the flow control properties on each port of the switch
- Keeps flow control disabled for all priorities on all ports by default
- Allows an administrator to enable or disable flow control per port and per priority level
- Supports flow control only on physical ports, not on logical interfaces such as tunnels or interfaces defined by sharing a physical port in multiple virtual switch contexts
- Uses the configured threshold values to set up the queue buffer spaces accordingly in the datapath
- Provides hardware abstraction layer callouts for the following:
  - Enabling or disabling of flow control on each port for each priority
  - Configuring the queue depth for each priority on each port
- Provides trace logs for execution upon error conditions and for any event notifications from the hardware or datapath. These trace logs are a useful aid in troubleshooting.
- Allows the administrator to configure the minimum and maximum threshold values for flow control. These configurations are applied globally on all ports and priorities.

Priority Based Flow Control (PFC) provides an enhancement to the existing pause flow control mechanism as described in 802.1X.

#### ➤ **To enable PFC globally:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable PFC globally on the switch. Run:

```
switch (config) # dcb priority-flow-control enable
This action might cause traffic loss while shutting down a port with priority-flow-control mode on
Type 'yes' to confirm enable pfc globally: yes
```

#### ➤ **To enable PFC per priority:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable PFC globally on the switch. Run:

```
switch (config) # dcb priority-flow-control enable
dcb priority-flow-control enable
This action might cause traffic loss while shutting down a port with priority-flow-control mode on
Type 'yes' to confirm enable pfc globally: yes
switch (config) #
```

**Step 4.** Choose the desirable priority you want to enable using the command `dcb priority-flow-control priority <pri[0..7]> enable`.

```
switch (config) # dcb priority-flow-control priority 5 enable
```

➤ **To enable PFC per interface:**

**Step 1.** Log in as admin.

**Step 2.** Change to config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Enable PFC globally on the switch. Run:

```
switch (config) # dcb priority-flow-control enable
```

**Step 4.** Choose the desirable priority you want to enable using the command `dcb priority-flow-control priority <pri[0..7]> enable`

```
switch (config) # dcb priority-flow-control 5 enable
```

**Step 5.** Change to Interface mode. Run:

```
switch (config) #
switch (config) # interface ethernet 1/1
switch (config interface ethernet 1/1) #
```

**Step 6.** Enable PFC for the specific interface:

```
switch (config interface ethernet 1/1) # dcb priority-flow-control mode on
```

## 5.10.2 Enhanced Transmission Selection (ETS)

Enhanced Transmission Selection (ETS) provides a common management framework for assignment of bandwidth to traffic classes, for weighted round robin (WRR) scheduling. If a traffic class does not use all the bandwidth allocated to it, other traffic classes can use that available bandwidth. This allows optimal utilization of the network capacity while prioritizing and providing the necessary resources.

The ETS feature has the following attributes:

- ETS global admin:
  - Enable (default) – scheduling mode is WRR according to the configured bandwidth-per-traffic class
  - Disable – scheduling mode is Strict Priority (SP)

- Bandwidth percentage for each traffic class: By default each traffic class gets an equal share

The default mapping of priority to traffic classes (per interface) is as follows:

- Priority 0,1 mapped to TC 0
- Priority 2,3 mapped to TC 1
- Priority 4,5 mapped to TC 2
- Priority 6,7 mapped to TC 3

TC0 and TC3 are lossy TCs, while TC1 and TC2 can be lossless as well as lossy. It is possible but not recommended to map PFC enabled priorities (lossless traffic) to those TC0 or TC3.

ETS is enabled by default (scheduling is WRR).

➤ **To set the scheduling mode to Strict Priority:**

**Step 1.** Run the command `dcb ets disable`.

```
switch (config) # no dcb ets enable
```

➤ **To configure the WRR bandwidth percentage:**

**Step 1.** Make sure ETS feature is enabled. Run:

```
switch (config) # dcb ets enable
```

**Step 2.** Choose the WRR bandwidth rate and distribution.

By default the WRR distribution function is equal 25% per TC. Changing the WRR bandwidth rate will cause a change in the distribution function, for example if you wish to schedule more traffic on TC-0, TC-1, TC-2 while reducing the amount of traffic sent on TC-3, run the command `dcb ets tc bandwidth`.

```
switch (config) # dcb ets tc bandwidth 30 30 30 10
show dcb ets
```

ETS enabled

| TC | Bandwidth |
|----|-----------|
| 0  | 30%       |
| 1  | 30%       |
| 2  | 30%       |
| 3  | 10%       |

Number of Traffic Class: 4  
switch (config) #

Traffic class priorities are <0-3>, where 0 is the lowest and 3 is the highest.

The sum of all traffic class bandwidth value (in percentage) should be 100, otherwise the command fails.

**Step 3.** Run the command `show dcb ets` to verify the configuration.

```
switch (config) # show dcb ets
ETS enabled
```

| TC | Bandwidth |
|----|-----------|
| 0  | 30%       |
| 1  | 30%       |
| 2  | 10%       |
| 3  | 30%       |

```
Number of Traffic Class: 4
switch (config) #
```

## 5.10.3 Commands

### 5.10.3.1 Enhanced Transmission Selection (ETS)

#### dcb ets enable

**dcb ets enable**  
**no dcb ets enable**

Sets the switch egress scheduling mode to be weighted round robin.  
 The no form of the command sets the switch egress scheduling mode to be strict priority.

| <b>Syntax Description</b> | N/A                                                                                                                                                                                                                                                                                                                                                                                   |    |           |   |     |   |     |   |     |   |     |

## dcb ets tc bandwidth

**dcb ets tc bandwidth** <tc-0> <tc-1> <tc-2> <tc-3>  
**no dcb ets tc bandwidth**

Configures the bandwidth limit of the traffic class.  
 The no form of the command sets the bandwidths per traffic class back to its default.

## vlan map-priority

**vlan map priority <priority> traffic-class <tc>**  
**no vlan map priority <priority>**

Maps an VLAN user priority to a traffic class.  
 The no form of the command sets the mapping back to default.

**Related Commands****Note**

### 5.10.3.2 Priority Flow Control (PFC)

#### dcb priority-flow-control enable

**dcb priority-flow-control enable [force]**  
**no dcb priority-flow-control enable [force]**

Enables PFC globally on the switch.  
 The no form of the command globally disables PFC on the switch.

| <b>Note</b>               | This command asks the user to approve traffic loss because there might be interfaces with dcb mode on, that will be shutdown.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                  |

## dcb priority-flow-control priority

**dcb priority-flow-control priority <prio> enable**  
**no dcb priority-flow-control priority <prio> enable**

Enables PFC per priority on the switch.  
 The no form of the command disables PFC per priority on the switch.

### Note

## 5.11 Access Control List

An Access Control List (ACL) is a list of permissions attached to an object, to filter or match switches packets. When the pattern is matched at the hardware lookup engine, a specified action (e.g. permit/deny) is applied. The rule fields represent flow characteristics such as source and destination addresses, protocol and VLAN ID.

ACL support currently allows actions of *permit* or *deny* rules, and supports only ingress direction. ACL search pattern can be taken from either L2 or L3 fields, e.g L2/L3 source and destination addresses, protocol, VLAN ID and priority or TCP port.

### 5.11.1 Configuring Access Control List

Access Control List (ACL) is configured by the user and is applied to a port once the ACL search engine matches search criteria with a received packet.

➤ **To configure ACL:**

**Step 1.** Log in as admin.

**Step 2.** Enter config mode. Run:

```
switch > enable
switch # configure terminal
```

**Step 3.** Create a MAC / IPv4 ACL (access-list) entity.

```
switch (config) mac access-list mac-acl
switch (config mac access-list mac-acl) #
```

**Step 4.** Add a MAC / IP rules to the appropriate access-list.

```
switch (config mac access-list mac-acl) seq-number 10 deny 0a:0a:0a:0a:0a:0a mask
ff:ff:ff:ff:ff:ff any vlan 6 cos 2 protocol 80
switch (config mac access-list mac-acl) #
```

**Step 5.** Bind the created access-list to an interface (slot/port or port-channel).

```
switch (config)
switch (config) # interface ethernet 1/1
switch (config interface ethernet 1/1) # mac port access-group mac-acl
```

### 5.11.2 ACL Actions

An ACL action is a set of actions can be activated in case the packet hits the ACL rule.

➤ **To modify the VLAN tag of the egress traffic as part of the ACL “permit” rule:**

**Step 1.** Create access-list action profile:

- a. Create an action access-list profile using the command `access-list action <action-profile-name>`
- b. Add rule to map a VLAN using the command `vlan-map <vlan-id>` within the action profile configuration mode

**Step 2.** Create an access-list and bind the action rule:

- a. Create an access-list profile using the command `ipv4/mac access-list`
- b. Add access list rule using the command `deny/permit (action <action profile name>)`

**Step 3.** Bind the access-list to an interface using the command `ipv4/mac port access-group`

Create an action profile and add vlan mapping action:

```
switch (config)#access-list action my-action
switch (config access-list action my-action) # vlan-map 20
switch (config access-list action my-action) #exit
```

Create an access list and bind rules:

```
switch (config)# mac access-list my-list
switch (config mac access-list my-list)# permit any any action my-action
switch (config mac access-list my-list)# exit
```

Bind an access-list to a port:

```
Switch (config)# interface ethernet 1/1
Switch (config interface ethernet 1/1)# mac port access-group my-list
```

## 5.11.3 Commands

### ipv4/mac access-list

**{ipv4 | mac} access-list <acl-name>**  
**no {ipv4 | mac} access-list <acl-name>**

Creates a MAC or IPv4 ACL and enter the ACL configuration mode.  
 The no form of the command deletes the ACL.

| <b>Related Commands</b>   | ipv4/mac access-list                                                                                               |                                            |
| <b>Note</b>               | The access control list should be defined prior to the binding action.                                             |                                            |

## deny/permit (MAC ACL rule)

**[seq-number <sequence-number>] {deny|permit} {any | <source-mac> [mask <mac>]} {any |<destination-mac> [mask <mac>]} [protocol <protocol>] [cos <cos-value>] [vlan <vlan-id> | vlan-mask <vlan-mask>] [action <action-id>]  
no <sequence-number>**

Creates a rule for MAC ACL.

The no form of the command deletes a rule from the MAC ACL.

## deny/permit (IPv4 ACL rule)

```
[seq-number <sequence-number>] {permit | deny} ip {<source-ip> [mask <ip>] |
[any]} {<dest-ip> [mask <ip>] | [any]} [action <action-id>]
no <sequence-number>
```

Creates a rule for IPv4 ACL.

The no form of the command deletes a rule from the IPv4 ACL.

|                           |                                                                                                                                                                            |                                                                                                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## deny/permit (IPv4 TCP/UDP ACL rule)

```
[seq-number <sequence-number>] {permit | deny} {tcp | udp} {<source-ip>
[mask <ip>] | [any]} {<dest-ip> [mask <ip>] | [any]} [eq-source <port-number>]
[eq-destination <port-number>] [action <action-id>]
no <sequence-number>
```

Creates a rule for IPv4 UDP/TCP ACL.

The no form of the command deletes a rule from the ACL.

## access-list action

**access-list action <action-profile-name>**  
**no access-list action <action-profile-name>**

Creates access-list action profile and entering the action profile configuration mode.  
 The no form of the command deletes the action profile.

## vlan-map

**vlan-map <vlan-id>**

**no vlan-map**

Adds action to map a new VLAN to the packet (in the ingress port or VLAN).  
The no form of the command removes the action to map a new VLAN.

## 5.12 Port Mirroring

Port mirroring enables data plane monitoring functionality which allows the user to send an entire traffic stream for testing. Port mirroring sends a copy of packets of a port's traffic stream, called "mirrored port", into an analyzer port. Port mirroring is used for network monitoring. It can be used for intrusion detection, security breaches, latency analysis, capacity and performance matters, and protocol analysis.

Figure 23 provides an overview of the mirroring functionality.

**Figure 23: Overview of Mirroring Functionality**

There is no limitation on the number of mirroring sources and more than a single source can be mapped to a single analyzer destination.

### 5.12.1 Mirroring Sessions

Port mirroring is performed by configuring mirroring sessions. A session is an association of a mirror port (or more) and an analyzer port.

**Figure 24: Mirror to Analyzer Mapping**

A mirroring session is a monitoring configuration mode that has the following parameters:

**Table 52 - Mirroring Parameters**

| Parameter             | Description                                                                  | Access |
|-----------------------|------------------------------------------------------------------------------|--------|
| Source interface(s)   | List of source interfaces to be mirrored.                                    | RW     |
| Destination interface | A single analyzer port through which all mirrored traffic egress.            | RW     |
| Header format         | The format and encapsulation of the mirrored traffic when sent to analyzer.  | RW     |
| Truncation            | Enabling truncation segments each mirrored packet to 64 bytes.               | RW     |
| Congestion control    | Controls the behavior of the source port when destination port is congested. | RW     |
| Admin state           | Administrative state of the monitoring session.                              | RW     |

### 5.12.1.1 Source Interface

The source interface (mirror port) refers to the interface from which the traffic is monitored. Port mirroring does not affect the switching of the original traffic. The traffic is simply duplicated and sent to the analyzer port. Traffic in any direction (either ingress, egress or both) can be mirrored.

There is no limitation on the number of the source interfaces mapped to a mirroring session.

Ingress and egress traffic flows of a specific source interface can be mapped to two different sessions.

### LAG

The source interface can be a physical interface or a LAG.

Port mirroring can be configured on a LAG interface but not on a LAG member. When a port is added to a mirrored LAG it inherits the LAG's mirror configuration. However, if port mirroring configuration is set on a port, that configuration must be removed prior to adding the port to a LAG interface.

When a port is removed from a LAG, the mirror property is switched off for that port.

### Control Protocols

All control protocols captured on the mirror port are forwarded to the analyzer port in addition to their normal treatment. For example LACP, STP, and LLDP are forwarded to the analyzer port in addition to their normal treatment by the CPU.

Exceptions to the behavior above are the packets that are being handled by the MAC layer, such as pause frames.

### 5.12.1.2 Destination Interface

The destination interface is an analyzer port is one to which mirrored traffic is sent. The mirrored packets, are duplicated, optionally modified and sent to the analyzer port. The SwitchX® platform supports up to 7 analyzer ports where any mirror port can be mapped to any analyzer port and more than a single mirror port can be mapped to a single analyzer port.

Packets can be forwarded to any destination using the command `destination interface`.  
The analyzer port supports status and statistics as any other port.

## LAG

The destination interface cannot be a member of LAG when the header format is local.

## Control Protocols

The destination interface may also operate in part as a standard port, receiving and sending out non-mirrored traffic. When the header format is configured as a local port, ingress control protocol packets that are received by the local analyzer port get discarded.

## Advanced MTU Considerations

The analyzer port, like its counterparts, is subject to MTU configuration. It does not send packets longer than configured.

When the analyzer port sends encapsulated traffic, the analyzer traffic has additional headers and therefore longer frame. The MTU must be configured to support the additional length, otherwise, the packet is truncated to the configured MTU.

The system on the receiving end of the analyzer port must be set to handle the egress traffic. If it is not, it might discard it and indicate this in its statistics (packet too long).

### 5.12.1.3 Header Format

Ingress traffic from the source interface can be manipulated in several ways depending on the network layout using the command `header -format`.

If the analyzer system is directly connected to the destination interface, then the only parameters that can be configured on the port are the MTU, speed and port based flow control. Priority flow control is not supported in this case. However, if the analyzer system is indirectly connected to the destination interface, there are two options for switching the mirrored data to the analyzer system:

- A VLAN tag may be added to the Ethernet header of the mirrored traffic
- An Ethernet header can be added with include a new destination address and VLAN tag

It must be taken into account that adding headers increases packet size.

**Figure 25: Header Format Options**

#### 5.12.1.4 Congestion Control

The destination ports might receive pause frames that lead to congestion in the switch port. In addition, too much traffic directed to the analyzer port (for example 40GbE mirror port is directed into 10G analyzer port) might also lead to congestion.

In case of congestion:

- When best effort mode is enabled on the analyzer port, SwitchX drops excessive traffic headed to the analyzer port using tail drop mechanism, however, the regular data (mirrored data heading to its original port) does not suffer from a delay or drops due to the analyzer port congestion.
- When the best effort mode on the analyzer port is disabled, the SwitchX does not drop the excessive traffic. This might lead to buffer exhaustion and data path packet loss.

The default behavior in congestion situations is to drop any excessive frames that may clog the system.

ETS, PFC and FC configurations do not apply to the destination port.

#### 5.12.1.5 Truncation

When enabled, the system can truncate the mirrored packets into smaller 64-byte packets (default) which is enough to capture the packets' L2 and L3 headers.

### 5.12.2 Configuring Mirroring Sessions

Figure 26 presents two network scenarios with direct and remote connectivity to the analyzer equipment. Direct connectivity is when the analyzer is connected to the analyzer port of the switch. In this case there is no need for adding an L2 header to the mirrored traffic. Remote connectivity is when the analyzer is indirectly connected to the analyzer port of the switch. In this situation, adding an L2 header may be necessary depending on the network's setup.

**Figure 26: Mirroring Session**

➤ **To configure a mirroring session:**

**Step 1.** Create a session. Run:

```
switch (config) # monitor session 1
```

This command enters a monitor session configuration mode. Upon first implementation the command also creates the session.

**Step 2.** Add source interface(s). Run:

```
switch (config monitor session 1) # add source interface ethernet 1/1 direction both
```

**Step 3.** Add destination interface. Run:

```
switch (config monitor session 1) # destination interface ethernet 1/2
```

**Step 4.** (Optional) Set header format. Run:

```
switch (config monitor session 1) # header-format add-ethernet-header destination-mac
00:0d:ec:f1:a9:c8 add-vlan 10 priority 5 traffic-class 2
```

For remote connectivity use the header formats add-vlan or add-ethernet-header. For local connectivity, use local.

**Step 5.** (Optional) Truncate the mirrored traffic to 64-byte packets. Run:

```
switch (config monitor session 1) # truncate
```

**Step 6.** (Optional) Set congestion control. Run:

```
switch (config monitor session 1) # congestion pause-excessive-frames
```

The default for this command is to drop excessive frames. The pause-excessive-frames option uses flow control to regulate the traffic from the source interfaces.

If the option `pause-excessive-frame` is selected, make sure that flow control is enabled on **all** source interfaces on the ingress direction of the monitoring session using the command `flowcontrol` in the interface configuration mode.

**Step 7.** Enable the session. Run:

```
switch (config monitor session 1) # no shutdown
```

### 5.12.3 Verifying Mirroring Sessions

➤ **To verify the attributes of a specific mirroring session:**

```
switch (config) # show monitor session 1
Admin: Enable
Status: Up
Truncate: Enable
Destination interface: eth1/2
Congestion type: pause-excessive-frames
Header format: add-ethernet-header
 - traffic class 2
 - vlan 10
 - priority 5
 - destination-mac 00:0d:ec:f1:a9:c8

Source interfaces
Interface direction

eth1/1 both
```

➤ **To verify the attributes of running mirroring sessions:**

```
switch (config) # show monitor session summary
```

| Session | Admin   | Status | Mode     | Destination | Source            |
|---------|---------|--------|----------|-------------|-------------------|
| 1       | Enable  | Up     | add-eth  | eth1/2      | eth1/1(b)         |
| 2       | Disable | Down   | add-vlan | eth1/2      | eth1/8(i), po1(e) |
| 3       | Enable  | Up     | add-eth  | eth1/5      | eth1/18(e)        |
| 7       | Disable | Down   | local    |             |                   |

5.12.4 Commands

5.12.4.1 Config

monitor session

**monitor session** <session-id>  
**no monitor session** <session-id>

Creates session and enters monitor session configuration mode upon using this command for the first time.  
The no form of the command deletes the session.

|                    |                                                                          |                                           |
|--------------------|--------------------------------------------------------------------------|-------------------------------------------|
| Syntax Description | session-id                                                               | The monitor session ID. The range is 1-7. |
| Default            | N/A                                                                      |                                           |
| Configuration Mode | Config                                                                   |                                           |

## 5.12.4.2 Config Monitor Session

### destination interface

**destination interface** <type> <number> [force]  
**no destination interface**

Sets the egress interface number.  
 The no form of the command deletes the destination interface.

|                           |                                                                                                              |                                                                  |
|---------------------------|--------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| <b>Syntax Description</b> | interface <type> <number>                                                                                    | Sets the interface type and number (e.g. ethernet 1/2)           |
|                           | force                                                                                                        | The user does not need to shutdown the port prior the operation. |
| <b>Default</b>            | no destination interface                                                                                     |                                                                  |

| <b>Role</b>               | admin                                                                                                                                                                        |                                                                                                                                                                                                                                                                                                                    |
| <b>Example</b>            | <pre>switch (config monitor session 1) # add source interface ethernet 1/1 direction both switch (config monitor session 1)#</pre>                                           |                                                                                                                                                                                                                                                                                                                    |
| <b>Related Commands</b>   |                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                    |
| <b>Note</b>               | If mirroring is configured in one direction (e.g. ingress) on an interface and then is configured in the other direction (e.g. egress), then the ultimate setting is “both”. |                                                                                                                                                                                                                                                                                                                    |

## header-format

**header-format** {local [traffic-class <tc>] | add-vlan <vlan-id> [priority <prio>]  
[traffic-class <tc>] | add-ethernet-header destination-mac <mac-address> [add-  
vlan <vlan-id> [priority <prio>]] [traffic-class <tc>]}  
**no header-format**

Sets the header format of the mirrored traffic.

The no form of the command resets the parameter values back to default.

| <b>Role</b>               | admin                                                                                                                                                                                      |                                                                |
| <b>Example</b>            | switch (config monitor session 1) # header-format add-ethernet-header<br>destination-mac 00:0d:ec:f1:a9:c8 add-vlan 10 priority 5 traffic-class<br>2<br>switch (config monitor session 1)# |                                                                |
| <b>Related Commands</b>   |                                                                                                                                                                                            |                                                                |
| <b>Note</b>               | If add-ethernet-header is used, the source MAC address is the one attached to the switch.                                                                                                  |                                                                |

## truncate

**truncate**  
**no truncate**

Truncates the mirrored frames to 64-byte packets.  
 The no form of the command disables truncation.

## 5.13 sFlow

sFlow (ver. 5) is a procedure for statistical monitoring of traffic in networks. MLNX-OS supports an sFlow sampling mechanism (agent), which includes collecting traffic samples and data from counters. The sFlow datagrams are then sent to a central collector.

The sampling mechanism must ensure that any packet going into the system has an equal chance of being sampled, irrespective of the flow to which it belongs. The sampling mechanism provides the collector with periodical information on the amount (and load) of traffic per interface by loading the counter samples into sFlow datagrams.

The sFlow packets are encapsulated and sent in UDP over IP. The UDP port number that is used is the standard 6343 by default.

**Figure 27: sFlow Functionality Overview**

### 5.13.1 Flow Samples

The sFlow agent samples the data path based on packets.

Truncation and sampling rate are the two parameters that influence the flow samples. In case of congestion the flow samples can be truncated to a predefined size before it is assigned to the CPU. The truncation can be set to any value between 64 to 256 bytes with the default being 128 bytes.

The sampling rate can be adjusted by setting an average rate. The system assures that a random number of packets is sampled, however, the sample rate on average converges to the configured rate. Valid values range between 4000 to 16777215 packets.

### 5.13.2 Statistical Samples

The sFlow agent samples interface counters time based. Polling interval is configurable to any value between 5-3600 seconds with the default being 20 seconds.

The following statistics are gathered by the CPU:

**Table 53 - List of Statistical Counters**

| Counter       | Description                                                  |
|---------------|--------------------------------------------------------------|
| Total packets | The number of packets that pass through sFlow-enabled ports. |

**Table 53 - List of Statistical Counters**

| Counter                     | Description                                                        |
|-----------------------------|--------------------------------------------------------------------|
| Number of flow samples      | The number of packets that are captured by the sampling mechanism. |
| Number of statistic samples | The number of statistical samples.                                 |
| Number of discarded samples | The number of samples that were discarded.                         |
| Number of datagrams         | The number of datagrams that were sent to the collector.           |

### 5.13.3 sFlow Datagrams

The sFlow datagrams contain flow samples and statistical samples.

The sFlow mechanism uses IP protocol, therefore if the packet length is more than the interface MTU, it becomes fragmented by the IP stack. The MTU may also be set manually to anything in the range of 200-9216 bytes. The default is 1400 bytes.

### 5.13.4 Sampled Interfaces

sFlow must be enabled on physical or LAG interfaces that require sampling. When adding a port to a LAG, sFlow must be disabled on the port. If a port with enabled sFlow is configured to be added to a LAG, the configuration is rejected. Removing a port from a LAG disables sFlow on the port regardless of the LAG's sFlow status.

### 5.13.5 Configuring sFlow

➤ *To configure the sFlow agent:*

**Step 1.** Unlock the sFlow commands. Run:

```
switch (config) # protocol sflow
```

**Step 2.** Enable sFlow on the system. Run:

```
switch (config) # sflow enable
```

**Step 3.** Enter sFlow configuration mode. Run:

```
switch (config) # sflow
switch (config sflow) #
```

**Step 4.** Set the central collector's IP. Run:

```
switch (config sflow) # collector-ip 10.10.10.10
```

**Step 5.** Set the agent-ip used in the sFlow header. Run:

```
switch (config sflow) # agent-ip 20.20.20.20
```

**Step 6.** (Optional) Set the sampling rate of the mechanism. Run:

```
switch (config sflow) # sampling-rate 16000
```

This means that one every 16000 packet gets collected for sampling.

**Step 7.** (Optional) Set the maximum size of the data path sample. Run:

```
switch (config sflow) # max-sample-size 156
```

**Step 8.** (Optional) Set the frequency in which counters are polled. Run:

```
switch (config sflow) # counter-poll-interval 19
```

**Step 9.** (Optional) Set the maximum size of the datagrams sent to the central collector. Run:

```
switch (config sflow) # max-datagram-size 1500
```

**Step 10.** Enable the sFlow agent on the desired interfaces. Run:

```
switch (config interface ethernet 1/1)# sflow enable
switch (config interface port-channel 1)# sflow enable
```

### 5.13.6 Verifying sFlow

➤ *To verify the attributes of the sFlow agent:*

```
switch (config)# show sflow

sflow protocol enabled
sflow enabled
sampling-rate 16000
max-sampled-size 156
counter-poll-interval 19
max-datagram-size 1500
collector-ip 10.10.10.10
collector-port 6343
agent-ip 20.20.20.20

Interfaces
Ethernet: eth1/1
Port-channel: po1

Statistics:
Total Packets: 2000
Number of flow samples: 1200
Number of samples discarded: 0
Number of statistic samples: 800
Number of datagrams: 300
```

## 5.13.7 Commands

### 5.13.7.1 Config

#### protocol sflow

**protocol sflow**  
**no protocol sflow**

Unhides the sFlow commands.  
The no form of the command deletes sFlow configuration and hides the sFlow commands.

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                   |
| <b>Default</b>            | Disabled                                              |
| <b>Configuration Mode</b> | Config                                                |
| <b>History</b>            | 3.3.3500                                              |
| <b>Role</b>               | admin                                                 |
| <b>Example</b>            | switch (config) # protocol sflow<br>switch (config) # |
| <b>Related Commands</b>   |                                                       |
| <b>Note</b>               |                                                       |

## **sflow enable (global)**

**sflow enable**  
**no sflow enable**

Enables sFlow in the system.  
The no form of the command disables sFlow without deleting the configuration.

|                           |                                                     |
|---------------------------|-----------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                 |
| <b>Default</b>            | Disabled                                            |
| <b>Configuration Mode</b> | Config                                              |
| <b>History</b>            | 3.3.3500                                            |
| <b>Role</b>               | admin                                               |
| <b>Example</b>            | switch (config) # sflow enable<br>switch (config) # |
| <b>Related Commands</b>   |                                                     |
| <b>Note</b>               |                                                     |

## sflow

### sflow

Enters sFlow configuration mode.

|                           |                                                    |
|---------------------------|----------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                |
| <b>Default</b>            | N/A                                                |
| <b>Configuration Mode</b> | Config                                             |
| <b>History</b>            | 3.3.3500                                           |
| <b>Role</b>               | admin                                              |
| <b>Example</b>            | switch (config) # sflow<br>switch (config sflow) # |
| <b>Related Commands</b>   |                                                    |
| <b>Note</b>               |                                                    |

### 5.13.7.2 Config sFlow

#### sampling-rate

**sampling-rate <rate>**  
**no sampling-rate**

Sets sFlow sampling ratio.  
 The no form of the command resets this parameter to its default value.

|                           |                                                                                |                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | rate                                                                           | Sets the number of packets passed before selecting one for sampling. The range is 4000-16777215. Zero disables sampling. |
| <b>Default</b>            | 16000                                                                          |                                                                                                                          |
| <b>Configuration Mode</b> | Config sFlow                                                                   |                                                                                                                          |
| <b>History</b>            | 3.3.3500                                                                       |                                                                                                                          |
| <b>Role</b>               | admin                                                                          |                                                                                                                          |
| <b>Example</b>            | <pre>switch (config sflow) # sampling-rate 16111 switch (config sflow) #</pre> |                                                                                                                          |
| <b>Related Commands</b>   |                                                                                |                                                                                                                          |
| <b>Note</b>               |                                                                                |                                                                                                                          |

## max-sample-size

**max-sample-size** <packet-size>

**no max-sample-size**

Sets the maximum size of sampled packets by sFlow.

The no form of the command resets the parameter to its default value.

|                           |                                                                                |                                                     |
|---------------------------|--------------------------------------------------------------------------------|-----------------------------------------------------|
| <b>Syntax Description</b> | packet-size                                                                    | The sampled packet size. The range is 64-256 bytes. |
| <b>Default</b>            | 128 bytes                                                                      |                                                     |
| <b>Configuration Mode</b> | Config sFlow                                                                   |                                                     |
| <b>History</b>            | 3.3.3500                                                                       |                                                     |
| <b>Role</b>               | admin                                                                          |                                                     |
| <b>Example</b>            | <pre>switch (config sflow) # max-sample-size 165 switch (config sflow) #</pre> |                                                     |
| <b>Related Commands</b>   |                                                                                |                                                     |
| <b>Note</b>               | Sampled payload beyond the configured size is discarded.                       |                                                     |

## counter-poll-interval

**counter-poll-interval <seconds>**

**no counter-poll-interval**

Sets the sFlow statistics polling interval.

The no form of the command resets the parameter to its default value.

|                           |                                                                             |                                                                                                                 |
|---------------------------|-----------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | seconds                                                                     | The sFlow statistics polling interval in seconds. Range is 5-3600 seconds. Zero disables the statistic polling. |
| <b>Default</b>            | 20 seconds                                                                  |                                                                                                                 |
| <b>Configuration Mode</b> | Config sFlow                                                                |                                                                                                                 |
| <b>History</b>            | 3.3.3500                                                                    |                                                                                                                 |
| <b>Role</b>               | admin                                                                       |                                                                                                                 |
| <b>Example</b>            | switch (config sflow) # counter-poll-interval 30<br>switch (config sflow) # |                                                                                                                 |
| <b>Related Commands</b>   |                                                                             |                                                                                                                 |
| <b>Note</b>               |                                                                             |                                                                                                                 |

## max-datagram-size

**max-datagram-size** <packet-size>

**no max-datagram-size**

Sets the maximum sFlow packet size to be sent to the collector.  
The no form of the command resets the parameter to its default value.

| <b>Note</b>               | This packet contains the data sample as well as the statistical counter data. |                                                                                            |

## collector-ip

**collector-ip** <ip-address> [udp-port <udp-port-number>]  
**no collector-ip** [<ip-address> udp-port]

Sets the collector's IP.

The no form of the command resets the parameters to their default values.

|                           |                                                                             |                                     |

| <b>Note</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 5.14 Transport Applications

### 5.14.1 RDMA over Converged Ethernet (RoCE)

#### 5.14.1.1 RoCE Overview

Remote Direct Memory Access (RDMA) is the remote memory management capability that allows server to server data movement directly between application memory without any CPU involvement. RDMA over Converged Ethernet (RoCE) is a mechanism to provide this efficient data transfer with very low latencies on loss-less Ethernet networks. With advances in data center convergence over reliable Ethernet, ConnectX® EN with RoCE uses the proven and efficient RDMA transport to provide the platform for deploying RDMA technology in mainstream data center application at 10GigE and 40GigE link-speed. ConnectX® EN with its hardware offload support takes advantage of this efficient RDMA transport (InfiniBand) services over Ethernet to deliver ultra-low latency for performance-critical and transaction intensive applications such as financial, database, storage, and content delivery networks. RoCE encapsulates IB transport and GRH headers in Ethernet packets bearing a dedicated ether type. While the use of GRH is optional within InfiniBand subnets, it is mandatory when using RoCE. Applications written over IB verbs should work seamlessly, but they require provisioning of GRH information when creating address vectors. The library and driver are modified to provide mapping from GID to MAC addresses required by the hardware.

##### 5.14.1.1.1 IP Routable (RoCEv2)

A straightforward extension of the RoCE protocol enables traffic to operate in layer 3 environments. This capability is obtained via a simple modification of the RoCE packet format. Instead of the GRH used in RoCE, routable RoCE packets carry an IP header which allows traversal of IP L3 Routers and a UDP header that serves as a stateless encapsulation layer for the RDMA Transport Protocol Packets over IP.

**Figure 28: RoCEv2 and RoCE Frame Format Differences**

The proposed RoCEv2 packets use a well-known UDP destination port value that unequivocally distinguishes the datagram. Similar to other protocols that use UDP encapsulation, the UDP source port field is used to carry an opaque flow-identifier that allows network devices to implement packet forwarding optimizations (e.g. ECMP) while staying agnostic to the specifics of the protocol header format.

Furthermore, since this change exclusively affects the packet format on the wire, and due to the fact that with RDMA semantics packets are generated and consumed below the AP applications can seamlessly operate over any form of RDMA service (including the routable version of RoCE as shown in Figure 2), in a completely transparent way<sup>1</sup>.

**Figure 29: RoCEv2 Protocol Stack**

#### 5.14.1.2 RoCE Configuration

In order to function reliably, RoCE requires a form of flow control. While it is possible to use global flow control, this is normally undesirable, for performance reasons.

The normal and optimal way to use RoCE is to use Priority Flow Control (PFC). To use PFC, it must be enabled on all endpoints and switches in the flow path.

In the following section we present instructions to configure PFC on Mellanox ConnectX™ cards. There are multiple configuration steps required, all of which may be performed via PowerShell. Therefore, although we present each step individually, you may ultimately choose to write a PowerShell script to do them all in one step. Note that administrator privileges are required for these steps.

For further information, please refer to the following URL:

<http://blogs.technet.com/b/josebda/archive/2012/07/31/deploying-windows-server-2012-with-smb-direct-smb-over-rdma-and-the-mellanox-connectx-3-using-10gbe-40gbe-roce-step-by-step.aspx>

##### 5.14.1.2.1 Prerequisites

The following are the driver's prerequisites in order to set or configure RoCE:

- ConnectX®-3 and ConnectX®-3 Pro firmware version 2.30.3000 or higher

1. Standard RDMA APIs are IP based already for all existing RDMA technologies

- All InfiniBand verbs applications which run over InfiniBand verbs should work on RoCE links if they use GRH headers.
- Set HCA to use Ethernet protocol:  
Display the Device Manager and expand “System Devices”.

#### 5.14.1.2.2 Configuring Windows Host

Since PFC is responsible for flow controlling at the granularity of traffic priority, it is necessary to assign different priorities to different types of network traffic. As per RoCE configuration, all ND/NDK traffic is assigned to one or more chosen priorities, where PFC is enabled on those priorities.

Configuring Windows host requires configuring QoS.

##### 5.14.1.2.2.1 Using Global Pause Flow Control (GFC)

- ***To use Global Pause Flow Control (GFC) mode, disable QoS and Priority:***

```
PS $ Disable-NetQosFlowControl
PS $ Disable-NetAdapterQos
```

#### 5.14.1.3 Configuring SwitchX® Based Switch System

- ***To enable RoCE, the SwitchX should be configured as follows:***
- Ports facing the host should be configured as access ports, and either use global pause or Port Control Protocol (PCP) for priority flow control
  - Ports facing the network should be configured as trunk ports, and use Port Control Protocol (PCP) for priority flow control

For further information on how to configure SwitchX, please refer to SwitchX User Manual.

#### 5.14.1.4 Configuring Router (PFC only)

The router uses L3's DSCP value to mark the egress traffic of L2 PCP. The required mapping, maps the three most significant bits of the DSCP into the PCP. This is the default behavior, and no additional configuration is required.

##### 5.14.1.4.1 Copying Port Control Protocol (PCP) Between Subnets

The captured PCP option from the Ethernet header of the incoming packet can be used to set the PCP bits on the outgoing Ethernet header.

#### 5.14.1.5 Configuring the RoCE Mode

Configuring the RoCE mode requires the following:

- RoCE mode is configured per-driver and is enforced on all the devices in the system

The supported RoCE modes depend on the firmware installed. If the firmware does not support the needed mode, the fallback mode would be the maximum supported RoCE mode of the installed NIC.

RoCE mode can be enabled and disabled via PowerShell.

➤ **To enable RoCE using the PowerShell:**

- Open the PowerShell and run:

```
Set-MlnxDriverCoreSetting -RocMode 1
```

➤ **To enable RoCEv2 using the PowerShell:**

- Open the PowerShell and run:

```
Set-MlnxDriverCoreSetting -RocMode 2
```

➤ **To disable any version of RoCE using the PowerShell:**

Open the PowerShell and run:

```
Set-MlnxDriverCoreSetting -RocMode 0
```

➤ **To check current version of RoCE using the PowerShell:**

**Step 1.** Open the PowerShell and run:

```
Get-MlnxDriverCoreSetting
```

**Step 2.** Example output:

```
Caption : DriverCoreSettingData 'mlx4_bus'
Description : Mellanox Driver Option Settings
.
.
.
RocMode : 0
```

## 6 IP Routing

### 6.1 General

#### 6.1.1 IP Interfaces

MLNX-OS supports 3 types of IP interfaces.

- VLAN interface
- Loopback interface
- Router ports

Router ports are not supported on SX10xx-xxxR and SX60xx-xxxR systems.

VLAN interface is a logical IPv4 interface created per subnet over a specific 802.1Q VLAN ID. If two hosts from two different subnets need to communicate (via the IP layer), the network administrator needs to configure two interface VLANs, one for each of the subnets. The user may configure up to 64 VLAN interfaces.

Each interface VLAN has the following attributes:

- Admin state
- Operational state
- MAC address
- IP address and mask
- MTU
- Description
- Set of counters

Loopback interface is a logical software entity where traffic transmitted to this interface is immediately received on the sending end.

Router port is a regular switch port configured to operate as an L3 interface. Router ports are assigned an IP address and all L3 commands become applicable to them.

Once configured, router ports no longer partake in the bridging activities of the switch and VLANs configured on them are separate from the pool allocated for the switch ports.

### 6.1.1.1 Commands

## switchport

**switchport [force]**  
**no switchport [force]**

Configures the Ethernet interface as a regular switchport.  
The no form of the command configures the Ethernet interface as a router port.

|                           |                                                              |                                                                      |
|---------------------------|--------------------------------------------------------------|----------------------------------------------------------------------|
| <b>Syntax Description</b> | force                                                        | Forces configuration even if the interface's admin state is enabled. |
| <b>Default</b>            | N/A                                                          |                                                                      |
| <b>Configuration Mode</b> | Config                                                       |                                                                      |
| <b>History</b>            | 3.3.5200                                                     |                                                                      |
| <b>Role</b>               | admin                                                        |                                                                      |
| <b>Example</b>            | switch (config interface ethernet 1/10)# no switchport force |                                                                      |
| <b>Related Commands</b>   |                                                              |                                                                      |
| <b>Note</b>               |                                                              |                                                                      |

## encapsulation dot1q vlan

**encapsulation dot1q vlan <vlan-id> [force]**

**no encapsulation dot1q vlan [force]**

Enables L2 802.1Q encapsulation of traffic on a specified router port in a VLAN.  
The no form of the command disables L2 802.1Q encapsulation of traffic on a specified router port in a VLAN.

|                           |                                                                      |                                                                        |
|---------------------------|----------------------------------------------------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | vlan-id                                                              | Enables L2 802.1Q encapsulation of traffic on a router port in a VLAN. |
|                           | force                                                                | Forces admin state down.                                               |
| <b>Default</b>            | N/A                                                                  |                                                                        |
| <b>Configuration Mode</b> | Config Interface Ethernet                                            |                                                                        |
| <b>History</b>            | 3.3.5200                                                             |                                                                        |
| <b>Role</b>               | admin                                                                |                                                                        |
| <b>Example</b>            | switch (config interface ethernet 1/10)# encapsulation dot1q vlan 10 |                                                                        |

### 6.1.2 Equal Cost Multi-Path Routing (ECMP)

Equal-cost multi-path routing (ECMP) is a routing strategy where next-hop packet forwarding to a single destination can occur over multiple paths.

In Figure 30, routers R1 and R2 can both access each of their router peer networks. Router R1 routing table for 10.0.40/24 will contain the following routes:

- 10.0.10.2
- 10.0.20.2
- 10.0.30.2

**Figure 30: ECMP**

The load balancing function of the ECMP is configured globally on the system.

Hash algorithm can be symmetric or asymmetric. In symmetric hash functions bidirectional flows between routes will follow the same path, while in asymmetric hash functions, bidirectional traffic can follow different paths in both directions.

The following load balancing types are supported:

- Source IP & Port – source IP (SIP) and source UDP/TCP port: If the packet is not UDP/TCP, only SIP is used for the hash calculation. This is an asymmetric hash function.
- Destination IP & Port – destination IP (DIP) and destination UDP/TCP port: If the packet is not UDP/TCP, only DIP is used for the hash calculation. This is an asymmetric hash function.
- Source and Destination IP & Port – destination and source IP, as well as destination and source UDP/TCP port: If the packet is not UDP/TCP, only SIP/DIP are used for the hash calculation. This is a symmetric hash function.
- Traffic Class: Load balance based on the traffic class assigned to the packet. This is an asymmetric hash function.
- All (default): all above fields are part of the hash calculations. This is a symmetric hash function.

### 6.1.2.1 Hash Functions

It is advised that LAG and ECMP hash function configuration over more than one hop is different. If the same hash function is used over two hops, all the traffic sorted from one hop to following one will arrive already having the same characteristics, which will render the next hash function useless. For example, configure load-balancing on the first hop based on source IP while on the next hop based on destination IP.

**Figure 31: Multiple Hash Functions**

### 6.1.3 IPv4 Routing Mode

The resources available for IPv4 routing are as follows:

- number of IPv4 neighbors – 2048
- number of IPv4 unicast routes – 4096
- number of IPv4 multicast routes – 672

Prior to upgrading to this software release the user must align the number of configured multicast routes to number defined above.

### 6.1.4 Creating an IP Interface

Preconditions:

- An L3 license must be installed on your system (UPGR-xxxx-GW)
- A VLAN must be created using the command `vlan <vlan-id>`
- There must be at least one interface attached to this VLAN (to do so, run the `switchport` command in the interface configuration mode)
- There must be at least one interface in the operational state “UP”

➤ **To create an IP interface:**

**Step 1.** Create a VLAN interface using the command `interface vlan <vlan-id>`.

**Step 2.** Apply an IP address and a network mask to the interface using the ip address command.

```
switch (config)# vlan 10
switch (config vlan 10)# exit
switch (config)# interface ethernet 1/1
switch (config interface ethernet 1/1)#switchport mode access
switch (config interface ethernet 1/1)#exit
switch (config)# show interface ethernet status // making sure there is a
 port in UP state
```

| Port        | Operational state | Speed   | Nego- |
|-------------|-------------------|---------|-------|
| tiation     |                   |         |       |
| ----        | -----             | -----   | ----  |
| -----       |                   |         |       |
| Eth1/1      | Up                | 40 Gbps | No-   |
| Negotiation |                   |         |       |
| ...         |                   |         |       |

```
switch (config)#interface vlan 10
switch (config interface vlan)#ip address 10.10.10.10 /24
switch (config interface vlan)#show interface vlan 10
```

```
Vlan 10
Admin state: Enabled
Operational state: UP
Mac Address: 00:02:c9:5d:e0:f0
Internet Address: 10.10.10.10/24
Broadcast address: 10.10.10.255
MTU: 1500 bytes
Description: my-ip-interface
Counters: disabled
switch (config interface vlan)#
```

## 6.1.5 Commands

### 6.1.5.1 General

#### ip routing

**ip routing**  
**no ip routing**

Enables L3 capabilities: IP router interfaces, static routing and routing protocols.  
The no form of the command disables L3 capabilities, however does not delete the L3 configuration.

|                           |                                                                                                                                                                                |

| <b>Note</b>               |                                                                               |

## 6.1.5.2 Interface VLAN

### interface vlan

**interface vlan <vlan-id>**  
**no interface vlan <vlan-id>**

Creates a VLAN interface and enters the interface VLAN configuration mode.  
 The no form of the command deletes the VLAN interface.

|                           |                                                                                                                                                                                                                                                                                                                                                                       |                           |

## ip address

**ip address** <ip-address> <mask>  
**no ip address** <ip-address> <mask>

Enters user-defined description for the interface.

|                           |                                                                                                                                                                                                                                                                                                                                                                                              |                                                                                                                                                                 |

## counters

**counters**  
**no counters**

Enables counters gathering on the IP interface.  
 The no form of the command disables counters gathering on the IP interface.

**ip icmp redirect**  
**no ip icmp redirect**

Enables ICMP redirect.  
 The no form of the command disables ICMP redirect.

| <b>Note</b>               | Byte counters count octets starting from the IP header field, it doesn't count the L2 header (MAC, VLAN) and FCS length.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                                          |

### 6.1.5.3 Loopback Interface

## interface loopback

**interface loopback <id>**  
**no interface loopback <id>**

Creates a loopback interface and enters the interface configuration mode.  
 The no form of the command deletes the interface.

|                           |                                                                                                                                                                                                                                                               |                         |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>Up to 32 loopback interfaces can be configured.</li> <li>Within the loopback configuration mode, you can configure description and ip-address.</li> <li>MTU cannot be configured on the loopback interface.</li> </ul> |                         |

## ip address

**ip address** <ip-address> <mask>  
**no ip address** <ip-address> <mask>

Enters user-defined description for the interface.

## description

**description** <string>

**no description**

Enters a description for the interface.

The no form of the command sets the description to default.

### 6.1.5.4 Routing and ECMP

## ip route

**ip route <IP prefix> <netmask> <next hop IP address>**  
**no ip route <IP prefix> <netmask> <next hop IP address>**

Sets a static route.  
 The no form of the command deletes the static route

| Syntax Description | IP address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | IPv4 address                                                                                                                                             |  |  |  |

| Note               | The IP prefix and the network mask must be aligned in the LSB mask, (for example 192.168.0.0 /16 or 192.168.10.0 /24, or 192.168.10.10 /32)                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                                                                                                                                          |  |  |  |

## ip load-sharing

**ip load-sharing <type>**

**no ip load-sharing**

This command sets the ECMP load sharing mode.

The no form of the command sets the load-sharing to default.

### 6.1.5.5 Network to Media Resolution (ARP)

#### ip arp

**ip arp <ip-address> <MAC-address>**  
**no ip arp <ip-address>**

Adds static ARP entry for the defined interface.  
 The no form of the command deletes the static ARP entry from the interface.

| Syntax Description        | IP address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             | IPv4 Address                           |

## ip arp timeout

**ip arp timeout <timeout-value>**

**no ip arp timeout**

Sets the dynamic ARP cache timeout.

The no form of the command sets the timeout to default.

| <b>Note</b>               | This value is used as the ARP timeout whenever a new IP interface is created.                                                                                                                                                                                                                                                                                                                            |                                                                            |

## clear ip arp

**clear ip arp** {[interface <type>] | [<IP-address>]}

Clears dynamic arp entries from the ARP table with possible filters.

| <b>Syntax Description</b> | Linux Ping options                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>            | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Configuration Mode</b> | Config                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>History</b>            | 3.1.0000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Role</b>               | admin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Example</b>            | <pre>switch (config) # ping 172.30.2.2 PING 172.30.2.2 (172.30.2.2) 56(84) bytes of data. 64 bytes from 172.30.2.2: icmp_seq=1 ttl=64 time=0.703 ms 64 bytes from 172.30.2.2: icmp_seq=2 ttl=64 time=0.187 ms 64 bytes from 172.30.2.2: icmp_seq=3 ttl=64 time=0.166 ms 64 bytes from 172.30.2.2: icmp_seq=4 ttl=64 time=0.161 ms 64 bytes from 172.30.2.2: icmp_seq=5 ttl=64 time=0.153 ms 64 bytes from 172.30.2.2: icmp_seq=6 ttl=64 time=0.144 ms ^C --- 172.30.2.2 ping statistics --- 6 packets transmitted, 6 received, 0% packet loss, time 5004ms rtt min/avg/max/mdev = 0.144/0.252/0.703/0.202 ms switch (config) #</pre> |
| <b>Related Commands</b>   | traceroute                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Note</b>               | <ul style="list-style-type: none"> <li>• Ping to IPv6 address is not supported.</li> <li>• When using -I option use the interface name + interface number, for example “ping -I vlan10”</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## traceroute

**traceroute** [-46dFITUnrAV] [-f first\_ttl] [-g gate,...] [-i device] [-m max\_ttl] [-N squeries] [-p port] [-t tos] [-l flow\_label] [-w waittime] [-q nqueries] [-s src\_addr] [-z sendwait] host [packetlen]

Traces the route packets take to a destination.

| Syntax | Description                                                                                                                                                                                                                                               |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -4     | Uses IPv4.                                                                                                                                                                                                                                                |
| -6     | Uses IPv6                                                                                                                                                                                                                                                 |
| -d     | Enables socket level debugging.                                                                                                                                                                                                                           |
| -F     | Sets DF ("do not fragment" bit) on.                                                                                                                                                                                                                       |
| -I     | Uses ICMP ECHO for tracerouting.                                                                                                                                                                                                                          |
| -T     | Uses TCP SYN for tracerouting.                                                                                                                                                                                                                            |
| -U     | Uses UDP datagram (default) for tracerouting.                                                                                                                                                                                                             |
| -n     | Does not resolve IP addresses to their domain names.                                                                                                                                                                                                      |
| -r     | Bypasses the normal routing and send directly to a host on an attached network.                                                                                                                                                                           |
| -A     | Performs AS path lookups in routing registries and print results directly after the corresponding addresses.                                                                                                                                              |
| -V     | Prints version info and exit.                                                                                                                                                                                                                             |
| -f     | Starts from the first_ttl hop (instead from 1).                                                                                                                                                                                                           |
| -g     | Routes packets throw the specified gateway (maximum 8 for IPv4 and 127 for IPv6).                                                                                                                                                                         |
| -i     | Specifies a network interface to operate with.                                                                                                                                                                                                            |
| -m     | Sets the max number of hops (max TTL to be reached). Default is 30.                                                                                                                                                                                       |
| -N     | Sets the number of probes to be tried simultaneously (default is 16).                                                                                                                                                                                     |
| -p     | Uses destination port. It is an initial value for the UDP destination port (incremented by each probe, default is 33434), for the ICMP seq number (incremented as well, default from 1), and the constant destination port for TCP tries (default is 80). |
| -t     | Sets the TOS (IPv4 type of service) or TC (IPv6 traffic class) value for outgoing packets.                                                                                                                                                                |
| -l     | Uses specified flow_label for IPv6 packets.                                                                                                                                                                                                               |

|    |                                                                                                                                                                                                      |
|----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| -w | Sets the number of seconds to wait for response to a probe (default is 5.0). Non-integer (float point) values allowed too.                                                                           |
| -q | Sets the number of probes per each hop. Default is 3.                                                                                                                                                |
| -s | Uses source src_addr for outgoing packets.                                                                                                                                                           |
| -z | Sets minimal time interval between probes (default is 0). If the value is more than 10, then it specifies a number in milliseconds, else it is a number of seconds (float point values allowed too). |

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>Traceroute for IPv6 is not supported</li> <li>The following flags are not supported: -6, -l, -A</li> <li>When using -i option use the interface name + interface number, for example “traceroute -i vlan10”</li> </ul>                                                                                                                                                                                                                                                       |

## tcpdump

```
tcpdump [-aAdeflLnNOPqRStuUvxX] [-c count] [-C file_size]
 [-E algo:secret] [-F file] [-i interface] [-M secret]
 [-r file] [-s snaplen] [-T type] [-w file]
 [-W filecount] [-y datalinktype] [-Z user]
 [expression]
```

Invokes standard binary, passing command line parameters straight through. Runs in foreground, printing packets as they arrive, until the user hits Ctrl+C.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

### 6.1.5.7 QoS

## qos map dscp-to-pcp preserve-pcp

**qos map dscp-to-pcp preserve-pcp**  
**no qos map dscp-to-pcp preserve-pcp**

Configures the router to copy PCP bits when transferring data from one subnet to another.

The no form of the command disables this ability.

|                           |                                                                                                                                                                                                                                                                                                                                           |

By activating the command the router preserves the PCP bits from one subnet to another subnet (PCP bits are copied).</li></ul> |

## 6.2 IPv6

To activate this feature please contact your Mellanox support representative.

IP version 6 (IPv6) is a routing protocol which succeeds IPv4. With the expansion of the Internet and data bases IPv6 addresses consist of 128 bits whose purpose is to allow networks to include a significantly higher number of nodes by increasing the pool of available unique IP addresses. IPv6 packets alleviate overhead and allow for future customizability.

Textual representations of IPv6 addresses consist of 128 bits made up from eight 16-bit hexadecimal numbers separated by colons. IPv6 addresses may be abbreviated as follows:

- You may omit leading zeros in each 16-bit sequence
- You may replace an entire sequence with a double colon if it equals zero

For example, these addresses represent the same IPv6 address:

- af23:0000:0000:0000:1284:037d:35ce:2401
- af23:0:0:0:1284:37d:35ce:2401
- af23::1284:37d:35ce:2401

IPv6 addresses typically denote a 64-bit network prefix and a 64-bit host address.

Only static IPv6 and ECMP are supported.

The number of static IPv6 addresses supported is 64.

### 6.2.1 Neighbor Discovery Protocol

Neighbor Discovery (ND) decides relationships between neighbors and replaces ARP, ICMP, and ICMP redirect in IPv4.

Five kinds of ICMPv6 packets are defined by ND:

- Neighbor advertisement
- Router advertisement
- Neighbor solicitation
- Router solicitation
- Redirect

ND checks whether a neighboring node's address has changed, whether the neighbor is still reachable, and also resolves the address of the neighbor which a packet is being forwarded to. ND is also useful for network nodes for discovering other nodes and performing basic link-layer configuration.

## 6.2.2 Configuring IPv6

**Figure 32: IPv6 Network**

### ➤ To configure Router1:

**Step 1.** Enable IP routing. Run:

```
switch (config)# ip routing
```

**Step 2.** Enable forwarding IPv6 unicast packets. Run:

```
switch (config)# ipv6 routing
```

**Step 3.** Configure the VLAN interfaces. Run:

```
switch (config)# interface vlan 10
switch (config interface vlan 10) # exit
switch (config)# interface vlan 30
switch (config interface vlan 30) # exit
switch (config)# interface vlan 50
switch (config interface vlan 50) # exit
```

**Step 4.** Enable IPv6 on the VLAN interfaces. Run:

```
switch (config)# interface vlan 10 ipv6 enable
switch (config)# interface vlan 30 ipv6 enable
switch (config)# interface vlan 50 ipv6 enable
```

**Step 5.** Configure IPv6 addresses for each one of the VLAN interfaces. Run:

```
switch (config)# interface vlan 10 ipv6 address 2101:db01::1 /64
switch (config)# interface vlan 30 ipv6 address 2103:db01::2 /64
switch (config)# interface vlan 50 ipv6 address 2105:db01::1 /64
```

**Step 6.** Configure IPv6 unicast. Run:

```
switch (config)# ipv6 route 2002:db01:: /64 2101:db01::2
```

**Step 7.** Configure IPv6 unicast. Run:

```
switch (config)# ipv6 route 2002:db01:: /64 2105:db01::2
```

### ➤ To configure Router2:

**Step 1.** Disable prefix mode on the CLI. Run:

```
switch (config)# no cli default prefix-mode enable
```

**Step 2.** Enable the VLANs on the system. Run:

```
switch (config)# vlan 10
switch (config vlan 10) # exit
switch (config)# vlan 20
switch (config vlan 20) # exit
switch (config)# vlan 50
switch (config vlan 50) # exit
```

**Step 3.** Configure the switch ports to accept the VLANs of which they are part only. Run:

```
switch (config)# interface ethernet 1/1 switchport access vlan 10 // port2
switch (config)# interface ethernet 1/2 switchport access vlan 50 // port8
switch (config)# interface ethernet 1/36 switchport access vlan 20 // port5
```

**Step 4.** Disable spanning tree. Run:

```
switch (config)# no spanning-tree
```

**Step 5.** Enable IP routing. Run:

```
switch (config)# ip routing
```

**Step 6.** Enable forwarding IPv6 unicast packets. Run:

```
switch (config)# ipv6 routing
```

**Step 7.** Configure the VLAN interfaces. Run:

```
switch (config)# interface vlan 10
switch (config interface vlan 10) # exit
switch (config)# interface vlan 20
switch (config interface vlan 20) # exit
switch (config)# interface vlan 50
switch (config interface vlan 50) # exit
```

**Step 8.** Enable IPv6 on the VLAN interfaces. Run:

```
switch (config)# interface vlan 10 ipv6 enable
switch (config)# interface vlan 20 ipv6 enable
switch (config)# interface vlan 50 ipv6 enable
```

**Step 9.** Configure IPv6 addresses for each one of the VLAN interfaces. Run:

```
switch (config)# interface vlan 10 ipv6 address 2101:db01::2 /64
switch (config)# interface vlan 20 ipv6 address 2102:db01::1 /64
switch (config)# interface vlan 50 ipv6 address 2105:db01::2 /64
```

**Step 10.** Configure IPv6 unicast. Run:

```
switch (config)# ipv6 route 2103:db01:: /64 2101:db01::1
```

**Step 11.** Configure IPv6 unicast. Run:

```
switch (config)# ipv6 route 2103:db01:: /64 2105:db01::1
```

➤ ***Ping neighbor to verify IPv6 configuration:***

```
switch (config)# ping6 2101:db01::2
PING 2101:db01::2(2101:db01::2) 56 data bytes
64 bytes from 2101:db01::2: icmp_seq=1 ttl=64 time=0.371 ms
64 bytes from 2101:db01::2: icmp_seq=2 ttl=64 time=0.620 ms
64 bytes from 2101:db01::2: icmp_seq=3 ttl=64 time=0.192 ms
64 bytes from 2101:db01::2: icmp_seq=4 ttl=64 time=0.277 ms
64 bytes from 2101:db01::2: icmp_seq=5 ttl=64 time=0.231 ms
```

## 6.2.3 Commands

### ipv6 enable

**ipv6 enable**  
**no ipv6 enable**

Assigns automatic local IPv6 address to the interface.  
 The no form of the command deassigns that automatic local address and disables IPv6 if no static IPv6 address has been assigned to the interface.

## ipv6 address

**ipv6 address** <ipv6-address> /<length>  
**no ipv6 address** <ipv6-address> [/<length>]

Enables IPv6 processing and assigns an IPv6 address to the interface.  
 The no form of the command removes the specified IPv6 address.

## ipv6 nd managed-config-flag

**ipv6 nd managed-config-flag**  
**no ipv6 nd managed-config-flag**

Sets the managed address configuration flag in IPv6 router advertisements.  
The no form of the command restores the default setting.

## ipv6 nd other-config-flag

**ipv6 nd other-config-flag**  
**no ipv6 nd other-config-flag**

Indicates that other configuration information is available via DHCPv6.  
 The no form of the command removes the other configuration flag.

## ipv6 nd prefix

**ipv6 nd prefix** <ipv6-address> /<length> [no-advertise] [no-autoconfig] [no-onlink] [valid-time {<time> | infinite}] [preferred-time {<time> | infinite}]  
**no ipv6 nd prefix** <prefix>

Configures inclusion for router advertisements (RAs) for neighbor.  
 The no form of the command removes the corresponding IPv6 nd prefix.

## ipv6 nd ra dns-servers lifetime

**ipv6 nd ra dns-servers lifetime {<time> | infinite}**

**no ipv6 nd ra dns-servers lifetime**

Sets the default value for the lifetime of any recursive DNS server (RDNSS) configured on the interface.

The no form of the command removes the lifetime value.

## ipv6 nd ra dns-server

**ipv6 nd ra dns-server <ip-address> [lifetime [<time> | infinite]]**

**no ipv6 nd ra dns-server [<ip-address>]**

Configures the IPv6 address of a preferred recursive DNS server (RDNSS) to include in the neighbor-discovery router advertisements (RAs).

The no form of the command removes the RDNSS from the configuration.

## ipv6 nd ra dns-suffix

**ipv6 nd ra dns-suffix <domain-name> [lifetime {<time> | infinite}]**  
**no ipv6 nd ra dns-suffix [<domain-name>]**

Creates a DNS search list (DNSSL) to include in the neighbor-discovery router advertisements (RAs)<sup>1</sup>.

The no form of the command resets the value of this parameter to its default.

1. As defined in RFC 6106.

## ipv6 nd ra dns-suffixes lifetime

**ipv6 nd ra dns-suffixes lifetime {<time> | infinite}**  
**no ipv6 nd ra dns-suffixes lifetime**

Creates a DNS search list (DNSSL) to include in the neighbor-discovery router advertisements (RAs)<sup>1</sup>.

The no form of the command resets the value of this parameter to its default.

1. As defined in RFC 6106.

## ipv6 nd ra hop-limit

**ipv6 nd ra hop-limit <limit>**

**no ipv6 nd ra hop-limit**

Sets a suggested hop-limit value to be included in route advertisement (RA) packets. The no form of the command resets the parameter to its default value.

## ipv6 nd ra interval max-period

**ipv6 nd ra interval max-period <time> [min-period <time>]**  
**no ipv6 nd ra interval**

Configures the interval between IPv6 router advertisement (RA) transmissions.  
 The no form of the command resets the parameter to its default value.

## ipv6 nd ra lifetime

**ipv6 nd ra lifetime <time>**

**no ipv6 nd ra lifetime**

Configures the value that the switch places in the router lifetime field of IPv6 router advertisements (RAs).

The no form of the command resets the parameter to its default value.

## ipv6 nd ra mtu suppress

**ipv6 nd ra mtu suppress**  
**no ipv6 nd ra mtu suppress**

Suppresses the router advertisement (RA) MTU option to ensure that all nodes on a link use the same MTU value.

The no form of the command restores the MTU option to enabled.

| <b>Note</b>               | If not suppressed, MTU of the interface is advertised.                                                                                      |

## ipv6 nd ra suppress

**ipv6 nd ra suppress [all]**

**no ipv6 nd ra suppress**

Suppresses periodic IPv6 router advertisement (RA) transmissions.  
The no form of the command restores the transmission of RAs.

|                           |                                                                                                                                             |                                                                                                 |

## ipv6 nd reachable-time

**ipv6 nd reachable-time <time>**

**no ipv6 nd reachable-time**

Sets the time period the switch includes in the reachable time field of out-going advertisements (RAs).

The no form of the command resets the parameter to its default value.

## ipv6 nd router-preference

**ipv6 nd router-preference {high | medium | low}**  
**no ipv6 nd router-preference**

Sets the value the switch enters in the default router preference (DRP) field of router advertisements (RAs) it sends.

The no form of the command resets the parameter to its default value.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>IPv6 hosts maintain a default router list from which to select a router for traffic to offlink destinations. The router's address is then saved in the destination cache. The neighbor discovery protocol (NDP) prefers routers that are reachable or probably reachable over routers whose reachability is unknown or suspect. For reachable or probably reachable routers, NDP can either select the same router every time or cycle through the router list. DRP values specify a host's preferred router.</li> <li>If router lifetime is zero, preference value must be medium</li> </ul> |

## ipv6 nd retrans-timer

**ipv6 nd retrans-timer <time>**

**no ipv6 nd retrans-timer**

Advertises the time between neighbor solicitation (NS) messages in ICMPv6 router advertisement messages.

The no form of the command resets the parameter to its default value.

## ipv6 nd dad attempts

**ipv6 nd dad attempts <number>**

**no ipv6 nd dad attempts**

Sets the number of consecutive neighbor solicitation messages sent for duplicate address detection (DAD) validation.

The no form of the command resets the value to its default.

|                           |                                                                                                                                             |                                                                                                                                 |

## ipv6 neighbor

**ipv6 neighbor** <ipv6-addr> {**ethernet** <port> | **port-channel** <port-channel> | **vlan** <vlan-id>} <mac\_addr>  
**no ipv6 neighbor** <ipv6-addr> [{**ethernet** <port> | **port-channel** <port-channel> | **vlan** <vlan-id>}]

Creates an IPv6 neighbor discovery cache static entry.  
 The no form of the command removes the specified static entry from the IPv6 neighbor discovery cache.

## ipv6 route

**ipv6 route <ipv6-address> /<length> <next-hop> [<distance>]**

**no ipv6 route <ipv6-address> /<length> [next-hop]**

Creates an IPv6 static route.

The no form of the command deletes static routes.

## ipv6 routing

**ipv6 routing**  
**no ipv6 routing**

Enables forwarding IPv6 unicast packets.  
 The no form of the command disables IPv6 unicast routing.

## show ipv6 interface

**show ipv6 interface** [{**ethernet** <port> | **port-channel** <port-channel> | **vlan** <vlan-id>}] **brief**

Displays the status of specified routed interfaces that are configured for IPv6.

## show ipv6 neighbors

**show ipv6 neighbors** [{**ethernet** <port> | **port-channel** <port-channel> | **vlan** <vlan-id>}] | <ipv6-addr> | **summary**]

Displays IPv6 neighbor discovery (ND) cache information.

|                           |                                                                                                                                                                                            |                                                              |

## show ipv6 route

**show ipv6 route** [<ipv6-addr> <prefix>] [connected | static | summary]

Displays IPv6 neighbor discovery (ND) cache information.

## 6.3 OSPF

Open Shortest Path First (OSPF) is a link-state routing protocol for IP networks. It uses a link state routing algorithm and falls into the group of interior routing protocols, operating within a single autonomous system (AS).

OSPF-speaking routers send Hello packets to all OSPF-enabled IP interfaces. If two routers sharing a common data link agree on certain parameters specified in their respective Hello packets, they become neighbors.

Adjacencies, which can be thought of as virtual point-to-point links, are formed between some neighbors. OSPF defines several network types and several router types. The establishment of an adjacency is determined by the types of routers exchanging Hellos and the type of network over which the Hello packets are exchanged.

Each router sends link-state advertisements (LSAs) over all adjacencies. The LSAs describe all of the router's links, or interfaces, the router's neighbors, and the state of the links. These links might be to stub networks (those without another router attached), to other OSPF routers, to networks in other areas, or to external networks (those learned from another routing process). Because of the varying types of link-state information, OSPF defines multiple LSA types.

Each router receiving an LSA from a neighbor records the LSA in its link-state database and sends a copy of the LSA to all of its other neighbors. By flooding LSAs throughout an area, all routers will build identical link-state databases.

When the databases are complete, each router uses the SPF algorithm to calculate a loop-free graph describing the shortest (lowest cost) path to every known destination, with itself as the root.

When all link-state information has been flooded to all routers in an area, and neighbors have verified that their databases are identical, it means the link-state databases have been synchronized and the route tables have been built. Hello packets are exchanged between neighbors as keepalives, and LSAs are retransmitted. If the network topology is stable, no other activity should occur.

For OSPF network design over Mellanox L2 VMS, please refer to [Mellanox Virtual Modular Switch Reference Guide](#).

### 6.3.1 Router ID

The router ID is a 32-bit number assigned to the router running the OSPF protocol. This number uniquely identifies the router within an Autonomous System.

Router ID can be configured statically, however, if it is not configured, then the default election is as follows:

- If a loopback interface already exists, the router ID takes the loopback IP address;
- Otherwise, the lowest IP address is elected as router ID

### 6.3.2 ECMP

Equal-cost multi-path (ECMP) routing is a routing strategy where next-hop packet forwarding to a single destination can occur over multiple paths. The OSPF link-state routing algorithm can find multiple routes to the same destination, all multiple routes are added to the routing table only if those routes are equal-cost routes.

In case there are several routes with different cost, only the route with the lowest cost is selected. In case there are multiple routes with the same lowest cost, all of them are used (up to maximum of 64 ECMP routes).

ECMP is not configurable but is enabled by default for OSPF.

### 6.3.3 Configuring OSPF

**Figure 33: OSPF Basic Topology**

#### Precondition steps:

The following configuration example refers to Router 2 in [Figure 33](#). The remainder of the routers in the figure are configured similarly.

It is recommended to disable STP before enabling OSPF. Use the command `no spanning-tree`.

**Step 1.** Make sure an L3 license is installed. For a list of the available licenses see [Section 2.4, “Licenses,”](#) on page 39.

**Step 2.** Enable IP routing functionality. Run:.

```
switch (config)# ip routing
```

**Step 3.** Enable the desired VLAN. Run:.

```
switch (config)# vlan 10
switch (config)# vlan 20
```

**Step 4.** Add this VLAN to the desired interface. Run:

```
switch (config)# interface ethernet 1/1
switch (config ethernet 1/1)# switchport access vlan 10
switch (config ethernet 1/1)# exit
switch (config)# interface ethernet 1/2
switch (config ethernet 1/2)# switchport access vlan 20
```

**Step 5.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 10
```

**Step 6.** Apply IP address to the VLAN interface. Run:

```
switch (config interface vlan 10)# ip address 10.10.10.2 /16
```

**Step 7.** Enable the interface. Run:

```
switch (config interface vlan 10)# no shutdown
```

**Step 8.** Create a second VLAN interface. Run:

```
switch (config)# interface vlan 20
```

**Step 9.** Apply IP address to the second VLAN interface. Run:

```
switch (config interface vlan 20)# ip address 10.10.20.2 /16
```

**Step 10.** Enable the second interface. Run:

```
switch (config interface vlan 20)# no shutdown
```

#### Basic OSPF Configuration:

**Step 1.** To enable OSPF configuration run:

```
switch (config)# protocol ospf
```

**Step 2.** To create a router OSPF instance run:

```
switch (config)# router ospf
```

Only one instance of OSPF is supported.

**Step 3.** Associate the VLAN interfaces to the OSPF area. Area 0 is the backbone area, run:

```
switch (config interface vlan 10)# ip ospf area 0
switch (config interface vlan 10)# exit
switch (config)# interface vlan 20
switch (config interface vlan 20)# ip ospf area 0
```

## 6.3.4 Verifying OSPF

➤ **To verify OSPF configuration and status:**

**Step 1.** Verify OSPF configuration and status. Run:

```
switch (config) # show ip ospf

Routing Process 1 with ID 10.10.10.10 vrf-default

Stateful High Availability disabled
Graceful-restart is not supported
Supports only single TOS (TOS 0) route
Opaque LSA not supported
OSPF Admin State is enabled
```

```

Redistributing External Routes: Disabled
Administrative distance 110
Reference Bandwidth is 40Gb
Initial SPF schedule delay 1 msec
SPF Hold time 10 msec
Maximum paths to destination 64
Router is not originating router LSA with maximum metric
Condition: Always
Number of external LSAs 0, checksum sum 0
Number of opaque AS LSAs 0,checksum sum 0
Number of areas is 1, 1 normal, 0 stub, 0 nssa
Number of active areas is 1, 1 normal, 0 stub, 0 nssa

Area (0.0.0.0) (Active)
Interfaces in this area: 2 Active Interfaces: 2
Passive Interfaces: 0
SPF Calculation has run 5 times
This area is Normal area
Number of LSAs: 1, checksum sum 7700

switch (config) #

```

- Step 2.** Verify the OSPF neighbors status. Make sure that each neighbor reaches FULL state with its peer to enable it take part in all dynamic routing changes in the network. Run:

```

switch (config) # show ip ospf neighbors

Neighbor 10.10.10.1, interface address 10.10.10.2
In the area 0.0.0.0 via interface Vlan 10
Neighbor priority is 1, State is FULL
BDR is 10.10.10.1
Options 0
Dead timer due in 35

Neighbor 10.10.20.1, interface address 10.10.20.2
In the area 0.0.0.0 via interface Vlan 20
Neighbor priority is 1, State is FULL
BDR is 10.10.20.1
Options 0
Dead timer due in 35

switch (config) #

```

**Step 3.** Verify the OSPF Interface configuration and status run:

```
switch (config) # show ip ospf interface

Interface Vlan is 10 Enabled, line protocol is Down
IP address 10.10.10.2, Mask 255.255.0.0
Process ID 1 VRF Default, Area 0.0.0.0
OSPF Interface Admin State is enabled
State DOWN, Network Type BROADCAST, Cost 1
Transmit delay 1 sec, Router Priority 1
No designated router on this network
No backup designated router on this network
Timer intervals (sec's): Hello 10, Dead 40, Wait 40, Retransmit 5
No authentication
Number of opaque link LSAs: 0, checksum sum 0

Interface Vlan is 20 Enabled, line protocol is Up
IP address 10.10.20.2, Mask 255.255.0.0
Process ID 1 VRF Default, Area 0.0.0.0
OSPF Interface Admin State is enabled
State DESIGNATED ROUTER, Network Type BROADCAST, Cost 1
Transmit delay 1 sec, Router Priority 1
No designated router on this network
No backup designated router on this network
Timer intervals (sec's): Hello 10, Dead 40, Wait 40, Retransmit 5
No authentication
Number of opaque link LSAs: 0, checksum sum 0

switch (config) #
```

## 6.3.5 Commands

### 6.3.5.1 Config

#### **protocol ospf**

**protocol ospf**  
**no protocol ospf**

Enables Open Shortest Path First Protocol (OSPF), and unhides the related OSPF commands.

The no form of the command deletes the OSPF configuration and hides the OSPF related commands.

|                           |                                |
|---------------------------|--------------------------------|
| <b>Syntax Description</b> | N/A                            |
| <b>Default</b>            | OSPF feature is disabled.      |
| <b>Configuration Mode</b> | Config                         |
| <b>History</b>            | 3.3.3500                       |
| <b>Role</b>               | admin                          |
| <b>Example</b>            | switch (config)# protocol ospf |
| <b>Related Commands</b>   | ip routing                     |
| <b>Note</b>               |                                |

## router ospf

**router ospf**  
**no router ospf**

Enters router OSPF configuration mode, and creates default OSPF instance if not exist.

The no form of the command deletes the OSPF instance.

|                           |                                                              |
|---------------------------|--------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                          |
| <b>Default</b>            | No router OSPF is created.                                   |
| <b>Configuration Mode</b> | Config                                                       |
| <b>History</b>            | 3.3.3500                                                     |
| <b>Role</b>               | admin                                                        |
| <b>Example</b>            | switch (config)# router ospf<br>switch (config router ospf)# |
| <b>Related Commands</b>   | N/A                                                          |
| <b>Note</b>               | Only one OSPF instance is supported.                         |

### 6.3.5.2 Config Router

## router-id

**router-id** <ip-address>  
**no router-id**

Sets Router ID for the OSPF instance.

The no form of the command causes automatic election of router ID by the router.

| Syntax Description        | ip-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | The Router id in IP address format. |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| <b>Default</b>            | <p>The router ID is a 32-bit number assigned to the router running the OSPF protocol. This number uniquely identifies the router within an Autonomous System. Router ID can be configured statically, however, if it is not configured, then the default election is as follows:</p> <ul style="list-style-type: none"> <li>• If a loopback interface already exists, the router ID takes the loopback IP address;</li> <li>• Otherwise, the lowest IP address is elected as router ID.</li> </ul> |                                     |
| <b>Configuration Mode</b> | Config OSPF Router                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                     |
| <b>History</b>            | 3.3.3500                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |                                     |
| <b>Role</b>               | admin                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                     |
| <b>Example</b>            | switch (config router ospf)# router-id 10.10.10.10                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                     |
| <b>Related Commands</b>   | N/A                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                     |
| <b>Note</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |                                     |

## shutdown

**shutdown**  
**no shutdown**

Disables the OSPF instance.  
 The no form of the command enables the OSPF instance.

|                           |                                       |
|---------------------------|---------------------------------------|
| <b>Syntax Description</b> | N/A                                   |
| <b>Default</b>            | Enable (no shutdown)                  |
| <b>Configuration Mode</b> | Config OSPF Router                    |
| <b>History</b>            | 3.3.3500                              |
| <b>Role</b>               | admin                                 |
| <b>Example</b>            | switch (config router ospf)# shutdown |
| <b>Related Commands</b>   | N/A                                   |
| <b>Note</b>               |                                       |

## auto-cost reference-bandwidth

**auto-cost reference-bandwidth <ref-bw>**

**no auto-cost reference-bandwidth**

Configures reference-bandwidth in Gb/s (Default) or Mb/s.  
The no form of the command resets this parameter to its default value.

|                           |                                                            |               |
|---------------------------|------------------------------------------------------------|---------------|
| <b>Syntax Description</b> | value                                                      | Range: 1-4294 |
| <b>Default</b>            | Gb/s                                                       |               |
| <b>Configuration Mode</b> | Config OSPF Router                                         |               |
| <b>History</b>            | 3.3.3500                                                   |               |
| <b>Role</b>               | admin                                                      |               |

| <b>Related Commands</b>   | N/A                                                        |               |
| <b>Note</b>               |                                                            |               |

## distance

**distance <value>**

**no distance**

Configures the OSPF route administrative distance.

The no form of the command resets this parameter to default.

|                           |                                           |                                               |
|---------------------------|-------------------------------------------|-----------------------------------------------|
| <b>Syntax Description</b> | value                                     | OSPF administrative distance. Range is 1-255. |
| <b>Default</b>            | 110                                       |                                               |
| <b>Configuration Mode</b> | Config OSPF Router                        |                                               |
| <b>History</b>            | 3.3.3500                                  |                                               |
| <b>Role</b>               | admin                                     |                                               |
| <b>Example</b>            | switch (config router ospf)# distance 100 |                                               |
| <b>Related Commands</b>   | N/A                                       |                                               |
| <b>Note</b>               |                                           |                                               |

## redistribute

**redistribute {bgp | direct | static}**  
**no redistribute {bgp | direct | static}**

Import routes from other routing protocols as well as any statically configured routers into OSPF.

The no form of the command disables the importing of the routes.

|                           |                                                             |                                         |
|---------------------------|-------------------------------------------------------------|-----------------------------------------|
| <b>Syntax Description</b> | direct                                                      | Redistribute directly connected routes. |
|                           | bgp                                                         | Redistribute routes from BGP protocol.  |
|                           | static                                                      | Redistribute static configured routes.  |
| <b>Default</b>            | Disable (no redistribution)                                 |                                         |
| <b>Configuration Mode</b> | Config OSPF Router                                          |                                         |
| <b>History</b>            | 3.2.1000                                                    |                                         |
| <b>Role</b>               | admin                                                       |                                         |
| <b>Example</b>            | switch (config router ospf)# redistribute direct            |                                         |
| <b>Related Commands</b>   | N/A                                                         |                                         |
| <b>Note</b>               | Routes from multiple protocols can be imported in parallel. |                                         |

## timers throttle spf

**timers throttle spf <spf-delay> <spf-hold>**

**no timers throttle spf**

Sets the OSPF throttle SPF timers.

The no form of the command resets the timers to default.

|                           |                                                           |                                                                                                                |
|---------------------------|-----------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | spf-delay                                                 | The interval by which SPF calculations delayed after a topology change reception. Range is 0-100 milliseconds. |
|                           | spf-hold                                                  | The minimum delay between two consecutive delay calculations. Range is 0-1000 milliseconds.                    |
| <b>Default</b>            | spf-delay: 1 millisecond<br>spf-hold: 10 millisecond      |                                                                                                                |
| <b>Configuration Mode</b> | Config OSPF Router                                        |                                                                                                                |
| <b>History</b>            | 3.3.3500                                                  |                                                                                                                |
| <b>Role</b>               | admin                                                     |                                                                                                                |
| <b>Example</b>            | switch (config router ospf)# timers throttle spf 100 1000 |                                                                                                                |
| <b>Related Commands</b>   | N/A                                                       |                                                                                                                |
| <b>Note</b>               |                                                           |                                                                                                                |

## area default-cost

**area <area-id> default-cost <cost>**

**no area <area-id> default-cost**

Specifies cost for the default summary route sent into an OSPF stub or not-so-stubby area (NSSA).

The no form of the command sets the cost to the default value.

|                           |                                                                                             |                                                              |
|---------------------------|---------------------------------------------------------------------------------------------|--------------------------------------------------------------|
| <b>Syntax Description</b> | area-id                                                                                     | OSPF area-id. Range is 0-4294967295.                         |
|                           | cost                                                                                        | The cost for the default summary route. Range is 1-16777215. |
| <b>Default</b>            | The summary route cost is based on the area border router that generated the summary route. |                                                              |
| <b>Configuration Mode</b> | Config OSPF Router                                                                          |                                                              |
| <b>History</b>            | 3.3.3500                                                                                    |                                                              |
| <b>Role</b>               | admin                                                                                       |                                                              |
| <b>Example</b>            | switch (config router ospf)# area 0 default-cost 100                                        |                                                              |
| <b>Related Commands</b>   | N/A                                                                                         |                                                              |
| <b>Note</b>               | Base cost for all calculation is 56GbE.                                                     |                                                              |

## area range

**area <area-id> range <ip-address> <prefix> [not-advertise]**  
**no area <area-id> range <ip-address> <prefix> [not-advertise]**

Consolidates and summarizes routes at an OSPF area boundary.  
 The no form of the command removes the ip-prefix range from summarization.

|                           |                                                           |                                                                      |
|---------------------------|-----------------------------------------------------------|----------------------------------------------------------------------|
| <b>Syntax Description</b> | area-id                                                   | OSPF area-ID. Range is 0-4294967295.                                 |
|                           | ip-address                                                | IP Address.                                                          |
|                           | not-advertise                                             | Suppresses routes that match the specified IP address.               |
|                           | prefix                                                    | Network prefix (in the format of /24, or 255.255.255.0 for example). |
| <b>Default</b>            | Disabled                                                  |                                                                      |
| <b>Configuration Mode</b> | Config OSPF Router                                        |                                                                      |
| <b>History</b>            | 3.3.3500                                                  |                                                                      |

| <b>Note</b>               |                                                           |                                                                      |

## area stub

**area <area-id> stub [no-summary]**  
**no area <area-id> [stub [no-summary]]**

Configures an area as an OSPF stub area (an area is created if non-existent).  
 The no form of the command removes the stub area configuration and changes the area to normal, or deletes the area (if stub is not used).

|                           |                                          |                                                          |

## area nssa

**area <area-id> nssa [default-information-originate [metric <m-value>] [metric-type <m-type>]] [nosummary] [translate type7 always]**  
**no area <area-id> nssa [default-information-originate ] [no-summary] [translate type7 always]**

Configures an area as an OSPF not-so-stubby (NSSA) area.  
 The no form of the command removes the NSSA area configuration and changes the area to default.

|                           |                                             |                                                                                  |

| <b>Note</b>               | An area can be either stub, NSSA or normal. |                                                                                  |

## summary-address

**summary-address** <ip-address> <prefix> [not-advertise]  
**no summary-address** <ip-address> <prefix> [not-advertise]

Creates aggregate addresses for the OSPF protocol.  
 The no form of the command disables the aggregation of the ip-address.

|                           |                                                              |                                                                      |

| <b>Note</b>               | Maximum of 1500 summarized IP addresses can be configured.   |                                                                      |

### 6.3.5.3 Interface

## ip ospf cost

**ip ospf cost <cost>**  
**no ip ospf cost <cost>**

Sets OSPF cost of sending packet of this interface.  
 The no form of the command resets this parameter to default.

|                           |                                                                                                                                             |                                                        |

## ip ospf dead-interval

**ip ospf dead-interval <seconds>**

**no ip ospf dead-interval**

Configures the interval during which at least one Hello packet must be received from a neighbor before the router declares that neighbor as down.

The no form of the command resets this parameter to its default.

|                           |                                                                                                                                             |                                                        |

## ip ospf hello-interval

**ip ospf hello-interval <seconds>**

**no ip ospf hello-interval**

Configures the interval between Hello packets that OSPF sends on the interface.  
The no form of the command resets this parameter to default.

## ip ospf priority

**ip ospf priority <number>**

**no ip ospf priority**

Configures the priority for this OSPF interface.

The no form of the command resets this parameter to default.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>Use the “ip ospf priority” command to set the router priority, which determines the designated router for this network. When two routers are attached to a network, both attempt to become the designated router.</li> <li>The router with the higher router priority takes precedence. If there is a tie, the router with the higher router ID takes precedence. A router with a router priority set to zero cannot become the designated router or backup designated router.</li> </ul> |                                                                     |

## ip ospf network

**ip ospf network <type>**

**no ip ospf network**

Sets the OSPF interface network type.

The no form of the command resets the interface network type to its default.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>The network type influences the behavior of the OSPF interface. An OSPF network type is usually broadcast, which uses OSPF multicasting capabilities. Under this network type, a designated router and backup designated router are elected. For point-to-point networks, there are only two neighbors and multicast is not required.</li> <li>All routers on the same network should have the same network type.</li> </ul> |                                                                                      |

## ip ospf retransmit-interval

**ip ospf retransmit-interval <seconds>**

**no ip ospf retransmit-interval**

Configures the time between OSPF link-state advertisement (LSA) retransmissions for adjacencies that belongs to the interface.

The no form of the command resets this parameter to its default.

## ip ospf passive-interface

**ip ospf passive-interface**  
**no ip ospf passive-interface**

Suppresses flooding of OSPF routing updates on an interface.  
 The no form of the command reverts the status to active OSPF interface.

## ip ospf transmit-delay

**ip ospf transmit-delay <seconds>**

**no ip ospf transmit-delay**

Sets the estimated time required to send an OSPF link-state update packet.  
The no form of the command resets this parameter to its default.

|                           |                                                                                                                                             |                                                          |

## ip ospf shutdown

**ip ospf shutdown**  
**no ip ospf shutdown**

Disables the OSPF instance on the interface.  
 The no form of the command enables the OSPF on this interface.

## ip ospf authentication-key

**ip ospf authentication-key [auth-type] <password>**  
**no ip ospf authentication-key**

To assign a password for simple password authentication for the OSPF.  
 The no form of the command deletes the simple password authentication key.

## ip ospf message-digest-key

**ip ospf message-digest-key <key-id> md5 [auth-type] <key>**  
**no ip ospf message-digest-key <key-id>**

Sets the message digest key for MD5 authentication.  
 The no form of the command deletes the key for MD5 authentication.

## ip ospf area

**ip ospf area <area-id>**

**no ip ospf area**

Sets OSPF area of this interface (and creates the area if non-existent).  
The no form of the command removes the interface from the area.

## show ip ospf neighbors

**show ip ospf neighbors [vlan <vlan-id>] [<neighbor-id>]**

Displays the OSPF related interface neighbor configuration.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                                                                      |

## show ip ospf request-list

**show ip ospf request-list <neighbor-id> vlan <vlan-id>**

Displays the OSPF list of all link-state advertisements (LSAs) requested by a router.

|                           |                                                                                                                                                                                                                                                                |                                                 |

## show ip ospf retransmission-list

**show ip ospf retransmission-list <neighbor-id> vlan <vlan-id>**

Displays the OSPF list of all link-state advertisements (LSAs) waiting to be resent to neighbors.

## 6.4 BGP

Border Gateway Protocol (BGP) is an exterior gateway protocol which is designed to transfer routing information between routers. It maintains and propagates a table of routes which designates network reachability among autonomous systems (ASs).

BGP neighbors, or peers, are routers configured manually to converse using the BGP protocol on top of a TCP session on port 179. A BGP speaker periodically sends keep-alive messages to maintain the connection. Network reachability includes such information as forwarding destinations (IPv4 or IPv6) together with a list of ASs that this information traverses and other attributes, so it becomes possible to construct a graph of AS connectivity without routing loops. BGP makes possible to apply policy rules to enforce connectivity graph.

BGP routers communicate through TCP connection on port 179. Connection between BGP neighbors is configured manually or can be established dynamically by configuring dynamic listen groups. When BGP runs between two peers in the same AS, it is referred to as Internal BGP (iBGP, or Interior Border Gateway Protocol). When it runs between separate ASs, it is called External BGP (eBGP, or Exterior Border Gateway Protocol). Both sides can initiate a connection, after the initial connectivity is created, BGP state machine drives both sides to enter into ESTABLISHED state where they can exchange UPDATE messages with reachability information.

### 6.4.1 State Machine

In order to make decisions in its operations with peers, a BGP peer uses a simple finite state machine (FSM) that consists of six states: Idle; Connect; Active; OpenSent; OpenConfirm; and Established. For each peer-to-peer session, a BGP implementation maintains a state variable that tracks which of these six states the session is in. The BGP protocol defines the messages that each peer should exchange in order to change the session from one state to another.

The first state is the “Idle” state. In “Idle” state, BGP initializes all resources, refuses all inbound BGP connection attempts and initiates a TCP connection to the peer. The second state is “Connect”. In the “Connect” state, the router awaits the TCP connection to complete and transitions to the “OpenSent” state if successful. If unsuccessful, it initializes the ConnectRetry timer and transitions to the “Active” state upon expiration. In the “Active” state, the router resets the ConnectRetry timer to zero and returns to the “Connect” state. In the “OpenSent” state, the router sends an Open message and waits for one in return in order to transition to the “OpenConfirm” state. KeepAlive messages are exchanged and, upon successful receipt, the router is placed into the “Established” state. In the “Established” state, the router can send/receive: KeepAlive; Update; and Notification messages to/from its peer.

### 6.4.2 Configuring BGP

**Figure 34: Basic BGP Configuration**

Follow these steps for basic BGP configuration on two switches (Router 1 and Router 2):

Preconditions:

**Step 1.** Make sure the license installed supports L3.

**Step 2.** Enable IP routing functionality. Run:

```
switch (config)# ip routing
```

**Step 3.** Enable the desired VLAN. Run:

```
switch (config)# vlan 10
```

The same VLAN must be configured on both switches.

**Step 4.** Add this VLAN to the desired interface. Run:

```
switch (config)# interface ethernet 1/1
switch (config ethernet 1/1)# switchport access vlan 10
```

**Step 5.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 10
```

**Step 6.** Apply IP address to the VLAN interface on Router 1. Run:

```
switch (config interface vlan 10)# ip address 10.10.10.1 /24
```

**Step 7.** Apply IP address to the VLAN interface on Router 2. Run:

```
switch (config interface vlan 10)# ip address 10.10.10.2 /24
```

**Step 8.** Enable the interface. Run:

```
switch (config interface vlan 10)# no shutdown
```

Configure BGP:

**Step 1.** Enable BGP. Run:

```
switch (config)# protocol bgp
```

**Step 2.** Configure an AS number that identifies the BGP router. Run:

```
switch (config)# router bgp 100
```

To run iBGP, the AS number of all remote neighbors should be similar to the local AS number of the configured router.

**Step 3.** Configure BGP Router 1 neighbor. Run:

```
switch (config router bgp 100)# neighbor 10.10.10.2 remote-as 100
```

**Step 4.** Configure BGP Router 2 neighbor. Run:

```
switch (config router bgp 100)# neighbor 10.10.10.1 remote-as 100
```

### 6.4.3 Verifying BGP

**Step 1.** Check the general status of BGP. Run:

```
switch (config)# show ip bgp summary
BGP router identifier 10.10.10.1, local AS number 100
BGP table version is 100, main routing table version 100
0 network entries using 0 bytes of memory
0 path entries using 0 bytes of memory
0 BGP AS-PATH entries using 0 bytes of memory
0 BGP community entries using 0 bytes of memory
0 BGP extended community entries using 0 bytes of memory
Neighbor V AS MsgRcvd MsgSent TblVer InQ OutQ Up/Down State/PfxRcd
10.10.10.2 0 100 100 76 3 0 0 00:0:10:19 ESTABLISHED
switch (config)#
BGP summary information for VRF default, address family IPv4
```

- Verify that the state of each BGP neighbor reached to ESTABLISHED state.
- In case the neighbor is disabled (shutdown). The state of the neighbor will be IDLE.
- BGP incoming and outgoing messages should be incremented.
- The AS number of each neighbor is the correct one.

**Step 2.** Check the status of the neighbors. Run:

```
switch (config)# show ip bgp neighbors
BGP neighbor is 10.10.10.2, remote AS 100, external link
 BGP version 0, remote router ID 0.0.0.0
 BGP State = ESTABLISHED
 Last read 0:00:00:00, last write 0:00:00:00, hold time is 180, keepalive
interval is 60 seconds
 Configured hold time is 180, keepalive interval is 60 seconds
 Minimum holdtime from neighbor is 0 seconds
switch (config)#
```

You should be able to see running BGP counters and ESTABLISHED state per active neighbor.

## 6.4.4 Commands

### 6.4.4.1 Config

#### protocol bgp

**protocol bgp**  
**no protocol bgp**

Enables BGP feature, and unhides BGP related commands.  
The no form of the command deletes all BGP configuration and hides BGP related commands.

|                           |                                                   |
|---------------------------|---------------------------------------------------|
| <b>Syntax Description</b> | N/A                                               |
| <b>Default</b>            | Disabled                                          |

| <b>Example</b>            | switch (config)# protocol bgp<br>switch (config)# |
| <b>Related Commands</b>   | ip routing                                        |
| <b>Note</b>               |                                                   |

## clear ip bgp

**clear ip bgp [{<ip-address> | all} [soft] [in | out]]**

Clears BGP learned routes from the BGP table and resets the connection to the neighbor.

|                           |                                                                                                                                                           |                                                                                                |

|                           | 3.3.5200                                                                                                                                                  | Updated description                                                                            |
| <b>Role</b>               | admin                                                                                                                                                     |                                                                                                |
| <b>Example</b>            | switch (config)# clear ip bgp all<br>switch (config)#                                                                                                     |                                                                                                |
| <b>Related Commands</b>   | N/A                                                                                                                                                       |                                                                                                |
| <b>Note</b>               | This command removes BGP IPv4 learned routes from the routing table, reads all routes from designated peers, and sends routes to those peers as required. |                                                                                                |

## router bgp

**router bgp <as-number>**  
**no router bgp <as-number>**

Creates and enters a BGP instance with the specified AS number.  
 The no form of the command deletes all router BGP instance configuration.

## 6.4.4.2 Config Router

### shutdown

**shutdown**  
**no shutdown**

Gracefully disables BGP protocol without removing existing configuration.  
The no form of the command enables BGP.

|                           |                                             |

| <b>Note</b>               |                                             |

## aggregate-address

**aggregate-address** <prefix> [summary-only] [as-set] [attribute-map]  
**no aggregate-address** <prefix> [summary-only] [as-set] [attribute-map]

Creates an aggregate route in the BGP database.  
 The no form of the command disables ECMP across AS paths.

## bestpath as-path multipath-relax

**bestpath as-path multipath-relax**  
**no bestpath as-path multipath-relax**

Enables ECMP across AS paths.  
 The no form of the command disables ECMP across AS paths.

## bgp fast-external-fallover

**bgp fast-external-fallover**  
**no bgp fast-external-fallover**

Terminates eBGP sessions of any directly adjacent peer without waiting for the hold-down timer to expire if the link used to reach the peer goes down.  
 The no form of the command waits for hold-down timer to expire before terminating eBGP sessions.

|                           |                                                                                                                             |

| <b>Related Commands</b>   | maximum-paths                                                                                                               |
| <b>Note</b>               | Although this feature improves BGP conversion time, it may cause instability in your BGP table due to a flapping interface. |

## bgp listen limit

**bgp listen limit <maximum>**  
**no bgp listen limit**

Limits the number of dynamic BGP peers allowed on the switch.  
 The no form of the command resets to the default value.

|                           |                                                      |                                                                                    |

## bgp listen range

**bgp listen range** <ip-prefix> <length> peer-group <peer-group-name> remote-as <as-number>

**no bgp listen range** <ip-prefix> <length>

Identifies a range of IP addresses from which the switch will accept incoming dynamic BGP peering requests.

After applying the no form of the command, the switch will no longer accept dynamic peering requests on the range.

| Note               | <ul style="list-style-type: none"><li>• To create a static peer group, use the command neighbor peer-group</li><li>• Neighbors in a dynamic peer group are configured as a group and cannot be configured individually.</li></ul> |                                           |

## bgp redistribute-internal

**bgp redistribute-internal**  
**no bgp redistribute-internal**

Enables iBGP redistribution into an interior gateway protocol (IGP).  
 The no form of the command disables iBGP redistribution into an interior gateway protocol (IGP).

## cluster-id

**cluster-id <ip-address>**  
**no cluster-id <ip-address>**

Configures the cluster ID in a cluster with multiple route reflectors.  
 The no form of the command resets the cluster ID for route reflector.

|                           |                                                        |                                                                                                                                                                                                                              |
|---------------------------|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | ip-address                                             | The route reflector cluster ID <ul style="list-style-type: none"> <li>• 0.0.0.1 to 255.255.255.255 Valid cluster ID number</li> <li>• 0.0.0.0 removes the cluster-ID from the switch (similar to “no cluster-id”)</li> </ul> |
| <b>Default</b>            | Cluster ID is the same as Router ID                    |                                                                                                                                                                                                                              |

| <b>Note</b>               |                                                        |                                                                                                                                                                                                                              |

## client-to-client reflection

**client-to-client reflection**  
**no client-to-client reflection**

The switch will be configured as a route reflector.  
The no form of the command stops the switch from being a route reflector

|                           |                                                             |

## distance

**distance <external> <internal> <local>**  
**no distance**

Sets the administrative distance of the routes learned through BGP.  
 The no form of the command resets the administrative distance its default.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                   |

## graceful-restart stalepath-time

**graceful-restart stalepath-time <interval>**

**no graceful-restart stalepath-time**

Configures the maximum time that stale routes from a restarting BGP neighbor are retained after a BGP session is reestablished with that peer.

The no form of the command resets to the default value.

## graceful-restart helper

**graceful-restart helper**  
**no graceful-restart helper**

Enables BGP graceful restart helper mode on the switch for all BGP neighbors. The no form of the command disables BGP graceful restart helper mode on the switch for all BGP neighbors.

|                           |                                                                                                                                                                                                                                                                                                         |

| <b>Related Commands</b>   | N/A                                                                                                                                                                                                                                                                                                     |
| <b>Note</b>               | <ul style="list-style-type: none"> <li>When graceful restart helper mode is enabled, the switch retains routes from neighbors capable of graceful restart while those neighbors are restarting BGP</li> <li>Individual neighbor configuration takes precedence over the global configuration</li> </ul> |

## maximum-paths

### maximum-paths [ibgp] <maximum-path>

Configures the maximum number of parallel eBGP/iBGP routes that the switch installs in the routing table.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>This command provides an ECMP parameter that controls the number of equal-cost paths that the switch installs in the routing table for each destination.</li> <li>The action is effective after BGP restart.</li> <li>If the parameter “ibgp” is not used, the setting is applied on routes learned from peers from other ASs; if “ibgp” is used, the setting is applied to routes learned from peers of the same AS.</li> </ul> |                                                       |

## neighbor advertisement-interval

**neighbor {<ip-address> | <peer-group-name>} advertisement-interval <delay>**  
**no neighbor {<ip-address> | <peer-group-name>} advertisement-interval**

Sets the minimum route advertisement interval (MRAI) between the sending of BGP routing updates.

The no form of the command disables this function.

## neighbor allowas-in

**neighbor {<ip-address> | <peer-group-name>} allowas-in [number]**  
**no neighbor {<ip-address> | <peer-group-name>} allowas-in**

Configures the switch to permit the advertisement of prefixes containing duplicate autonomous switch numbers (ASNs).

The no form of the command disables this function.

| <b>Related Commands</b>   | ip routing<br>router bgp <as-number>                                                                                           |                                                           |
| <b>Note</b>               | Neighbors from the same AS as the router are considered as iBGP peers, and neighbors from other ASs are considered eBGP peers. |                                                           |

## neighbor description

**neighbor** {<ip-address> | <peer-group-name>} **description** <string>  
**no neighbor** {<ip-address> | <peer-group-name>} **description**

Associates descriptive text with the specified peer or peer group.  
 The no form of the command removes the description from the peer.

## neighbor ebgp-multihop

**neighbor** {<ip-address> | <peer-group-name>} **ebgp-multihop** [<ttl>]  
**no neighbor** {<ip-address> | <peer-group-name>} **ebgp-multihop**

Enables BGP to connect to external peers that are not directly connected to the switch.  
 The no form of the command applies the system disables connecting to external peers.

| <b>Related Commands</b>   | ip routing<br>neighbor <ip-address> remote-as <as-number>                                                  |                                         |
| <b>Note</b>               | The command does not establish the multi-hop if the only route to the peer is the default route (0.0.0.0). |                                         |

## neighbor export-localpref

**neighbor** {<ip-address> | <peer-group-name>} **export-localpref** <value>  
**no neighbor** {<ip-address> | <peer-group-name>} **export-localpref**

Configures the local preference value sent to the specified peer or peer group.  
 The no form of the command resets the local preference to its default value.

## neighbor graceful-restart helper

**neighbor {<ip-address> | <peer-group-name>} graceful-restart helper**  
**no neighbor {<ip-address> | <peer-group-name>} graceful-restart helper**

Enables BGP graceful restart helper mode for the specified BGP neighbor or peer group.

The no form of the command

## neighbor import-localpref

**neighbor** {<ip-address> | <peer-group-name>} **import-localpref** <value>  
**no neighbor** {<ip-address> | <peer-group-name>} **import-localpref**

Configures the local preference value assigned to routes received from the specified peer or peer group.

The no form of the command resets the local preference to its default value.

## neighbor local-as

**neighbor {<ip-address> | <peer-group-name>} local-as <as-id> [no-prepend | replace-as]**

**no neighbor {<ip-address> | <peer-group-name>} local-as**

Enables the modification of the AS path attribute for routes received from an eBGP neighbor.

The no form of the command disables AS path modification for the specified peer or peer group.

## neighbor maximum-prefix

**neighbor** {<ip-address> | <peer-group-name>} **maximum-prefix** <maximum>  
[warning-only]

**no neighbor** {<ip-address> | <peer-group-name>} **maximum-prefix**

Configures the number of BGP routes the switch accepts from a specified neighbor and defines an action when the limit is exceeded.

The no form of the command removes the limitation

## neighbor next-hop-peer

**neighbor {<ip-address> | <peer-group-name>} next-hop-peer**  
**no neighbor {<ip-address> | <peer-group-name>} next-hop-peer**

Configures the switch to list the peer address as the next hop in routes that it receives from the specified peer BGP-speaking neighbor or members of the specified peer group.

The no form of the command disables this function.

| <b>Note</b>               | This command overrides the next hop for all routes received from this neighbor or peer group |                             |

## neighbor next-hop-self

**neighbor {<ip-address> | <peer-group-name>} next-hop-self**  
**no neighbor {<ip-address> | <peer-group-name>} next-hop-self**

Configures the IP address of the router as the next hop address in routes advertises to the specific neighbor.

The no form of the command resets this parameter to its default.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>This function is used in networks where BGP neighbors do not directly access all other neighbors on the same subnet.</li> <li>In the default state, the next hop is generated based on the IP address and the present next hop in the route information.</li> </ul> |                             |

## neighbor password

**neighbor** {<ip-address> | <peer-group-name>} password [<encryption>]  
<string>

**no neighbor** {<ip-address> | <peer-group-name>} password

Enables authentication on a TCP connection with a BGP peer.  
The no form of the command resets the value to its default.

## neighbor peer-group

1. **neighbor** {<ip-address>} **peer-group** <peer-group-name>
2. **neighbor** {<peer-group-name>} **peer-group**
3. **no neighbor** {<ip-address>} **peer-group** <peer-group-name>
4. **no neighbor** {<peer-group-name>} **peer-group** <peer-group-name>

1. Assigns BGP neighbors to an existing peer group.
2. Creates a peer-group
3. Unassigns BGP neighbors to an existing peer group.
4. Removes a specified neighbor from the peer group

| Syntax Description | ip-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  | IP address of the neighbor |

| Note               | <ul style="list-style-type: none"><li>Once a peer group is created, the group name can be used as a parameter in neighbor configuration commands, and the configuration will be applied to all members of the group.</li><li>Settings applied to an individual neighbor in the peer group override group settings.</li><li>A neighbor can only belong to one peer group, so issuing this command for a neighbor that is already a member of another group removes it from that group.</li><li>When a neighbor is removed from a peer group, the neighbor retains the configuration inherited from the peer group.</li></ul> |                            |

## neighbor remote-as

**neighbor {<ip-address>} remote-as <as-number>**  
**no neighbor {<ip-address>} remote-as <as-number>**

Configures a neighbor.

The no form of the command removes the neighbor, dropping the connection and all routes if already connected.

| <b>Note</b>               | Neighbors from the same AS as the router are considered as iBGP peers, and neighbors from other ASs are considered eBGP peers. |                                         |

## neighbor remove-private-as

**neighbor {<ip-address> | <peer-group-name>} remove-private-as**  
**no neighbor {<ip-address> | <peer-group-name>} remove-private-as**

Removes private autonomous system numbers from outbound routing updates for external BGP (eBGP) neighbors.

The no form of the command preserves private AS numbers for the specified peer.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• This can only be used with external BGP (eBGP) peers.</li> <li>• If the update has only private AS numbers in the AS path, BGP removes these numbers.</li> <li>• If the AS path includes both private and public AS numbers, BGP does not remove the private AS numbers. This situation is considered a configuration error.</li> <li>• If the AS path contains the AS number of the eBGP neighbor, BGP does not remove the private AS number.</li> <li>• If the AS path contains confederations, BGP removes the private AS numbers only if they come after the confederation portion of the AS path.</li> </ul> |                       |

## neighbor route-map

```
neighbor {<ip-address> | <peer-group-name>} route-map <route-map-name>
[in | out]
no neighbor {<ip-address> | <peer-group-name>} route-map <route-map-name>
[in | out]
```

Configures a route map to inbound BGP routes.  
The no form of the command undoes the configuration.

## neighbor route-reflector-client

**neighbor {<ip-address> | <peer-group-name>} route-reflector-client**  
**no neighbor {<ip-address> | <peer-group-name>} route-reflector-client**

Sets the neighbor as a client but does not set up the reflection itself.  
 The no form of the command disables route reflection for the specific peer.

## neighbor send-community

**neighbor {<ip-address> | <peer-group-name>} send-community**  
**no neighbor {<ip-address> | <peer-group-name>} send-community**

Configures the switch to send community attributes to the specified BGP neighbor. The no form of the command disables sending community attributes for the specified peer.

## neighbor shutdown

**neighbor {<ip-address> | <peer-group-name>} shutdown**  
**no neighbor {<ip-address> | <peer-group-name>} shutdown**

Disables BGP neighbor gracefully.  
 The no form of the command enables BGP neighbor.

|                           |                                                                                                     |                             |
|---------------------------|-----------------------------------------------------------------------------------------------------|-----------------------------|
| <b>Syntax Description</b> | ip-address                                                                                          | IP address of the neighbor. |

| <b>Role</b>               | admin                                                                                               |                             |
| <b>Example</b>            | switch (config router bgp 100)# neighbor 10.10.10.10 shutdown                                       |                             |
| <b>Related Commands</b>   | N/A                                                                                                 |                             |
| <b>Note</b>               | Disabling a neighbor terminates all its active sessions and removes associated routing information. |                             |

## neighbor soft-reconfiguration inbound

**neighbor {<ip-address> | <peer-group-name>} soft-reconfiguration inbound**  
**no neighbor {<ip-address> | <peer-group-name>} soft-reconfiguration inbound**

Disables BGP neighbor gracefully.

The no form of the command restores the system default behavior (retaining all routes from the specified neighbor or group).

|                           |                                                                                                                                                                                                                                                                                                                                                                                 |                             |

## neighbor timers

**neighbor {<ip-address> | <peer-group-name>} timers <keep-alive> <hold-time>**  
**no neighbor {<ip-address> | <peer-group-name>} timers**

Configures the keepalive and hold times for a specified peer.  
 The no form of the command resets the parameters to their default values.

## neighbor transport connection-mode passive

**neighbor {<ip-address> | <peer-group-name>} transport connection-mode passive**

**no neighbor {<ip-address> | <peer-group-name>} transport connection-mode passive**

Sets the TCP connection for the specified BGP neighbor or peer group to passive mode.

The no form of the command sets the specified BGP neighbor or peer group to active connection mode.

## neighbor update-source

**neighbor <ip-address> update-source {ethernet <slot/port> | loopback <number> | port-channel <number> | vlan <vlan-id>}**  
**no neighbor <ip-address> update-source**

Configures the source-address for routing updates and to establish TCP connections with peers.

The no form of the command disables configured source-address for routing updates and for TCP connection establishment with a peer.

## neighbor weight

**neighbor {<ip-address> | <peer-group-name>} weight <value>**

**no neighbor {<ip-address> | <peer-group-name>} weight**

Assigns a weight attribute to paths from the specified neighbor.  
The no form of the command resets to default values.

## network

**network** <ip-prefix> <length> [<route-map-name>]

**no network** <ip-prefix> <length> [<route-map-name>]

Configures a route for advertisement to BGP peers.

The no form of the command removes the route from the BGP routes table, preventing its advertisement. The route is only advertised if the router has a gateway to the destination.

## redistribute

**redistribute {connected | static | ospf | ospf-internal | ospf-external} [<route-map>]**

**no redistribute {connected | static | ospf}**

Enables redistribution of specified routes to the BGP domain.  
The no form of the command disables route redistribution from the specified source.

## router-id

**router-id <ip-address>**

**no router-id**

Configures a fixed router ID for BGP.

The no form of the command removes the fixed router ID and restores the system default.

| Syntax Description        | ip-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   | IP Address identified the router ID |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| <b>Default</b>            | <p>The Router ID is dynamically elected (no router-id).</p> <ul style="list-style-type: none"> <li>• If a loopback interface is configured, the router ID is set to the IP address of the loopback interface.</li> <li>• If multiple loopback interfaces are configured, the router ID is set to the IP address of the loopback interface with the highest IP address.</li> <li>• If no loopback interface is configured, the router ID is set to the highest IP address on a physical interface.</li> </ul> |                                     |
| <b>Configuration Mode</b> | Config Router BGP                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |                                     |

| <b>Example</b>            | switch (config router bgp 100)# router-id 10.10.10.10                                                                                                                                                                                                                                                                                                                                                                                                                                                        |                                     |
| <b>Related Commands</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |                                     |
| <b>Note</b>               | The IP address configured identifies the BGP speaker. The command triggers an automatic notification and session reset for the BGP neighbors.                                                                                                                                                                                                                                                                                                                                                                |                                     |

## timers bgp

**timers bgp <keep-alive> <hold>**  
**no timers bgp**

Configures the BGP keepalive and hold times.  
 The no form of the command resets the parameters to their default settings.

## 6.4.5 IP AS-Path Access-List

### 6.4.5.1 Commands

#### ip as-path access-list

**ip as-path access-list <list-name> {permit | deny} <reg-exp> [any | egp | igp | incomplete]**  
**no ip as-path access-list <list-name>**

Creates an access list to filter BGP route updates.  
 The no ip as-path access-list command deletes the named access list.

## 6.5 Policy Rules

### 6.5.1 Route Map

Route maps define conditions for redistributing routes between routing protocols. A route map clause is identified by a name, filter type (permit or deny) and a sequence number. Clauses with the same name are components of a single route map; the sequence number determines the order in which the clauses are compared to a route.

### 6.5.1.1 Commands

## route-map

**route-map <map-name> [deny | permit] [sequence-number]**  
**no route-map <map-tag> {deny | permit} [<sequence-number>]**

Creates a route map that can be used for importing, exporting routes and applying local policies.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• All changes in a the route map configuration mode become pending until the end of the route-map session.</li> <li>• If not configured, deny   permit is configured as permit.</li> <li>• If not configured, sequence-number default value is 10.</li> </ul> |                                                  |

## continue <sequence-number>

**continue <sequence-number>**

**no continue**

Enables additional route map evaluation of routes whose parameters meet the clause's matching criteria.

The no form of the command removes this configuration from the route map clause.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>A clause typically contains a match (route-map) and a set (route-map) statement. The evaluation of routes whose settings are the same as match statement parameters normally end and the clause's set statement are applied to the route. Routes that match a clause containing a continue statement are evaluated against the clause specified by the continue statement.</li> <li>When a route matches multiple route-map clauses, the filter action (deny or permit) is determined by the last clause that the route matches. The set statements in all clauses matching the route are applied to the route after the route map evaluation is complete. Multiple set statements are applied in the same order by which the route was evaluated against the clauses containing them.</li> <li>Continue cannot be set to go back to a previous clause; &lt;sequence-number&gt; of the continue must always be higher than the current clause's sequence number.</li> </ul> |

## abort

### abort

Discards pending changes and returns to global configuration mode.

## match as-number

**match as-number <number>**

**no match as-number**

Filters according to one of the AS numbers in the AS path of the route.  
The no form of the command removes this configuration from the route map clause.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>When a clause contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each match statement.</li> <li>When a route's properties do not equal the statement parameters, the route is evaluated against the next clause in the route map, as determined by sequence number.</li> <li>If all clauses fail to permit or deny the route, the route is denied.</li> </ul> |                                    |

## match as-path

**match as-path** <as-path-list name>

**no match as-path**

Creates a route map clause entry that matches the route's AS path using an as-path access-list.

The no form of the command removes the match statement from the configuration mode route map clause.

## match community

**match community** <list-of-communities> [exact-match]

**no match community** <list-of-communities>

Creates a route map clause entry that matches a route if it contains at least the specified communities.

The no form of the command removes the match clause.

## match community-list

**match community <communities-list-name> exact-match**  
**no match community <communities-list-name> exact-match**

Creates a route map clause entry that specifies one route filtering condition  
 The no form of the command removes the match clause.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• When a clause contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each match statement.</li> <li>• When a route's properties do not equal the statement parameters, the route is evaluated against the next clause in the route map, as determined by sequence number.</li> <li>• If all clauses fail to permit or deny the route, the route is denied.</li> </ul> |

## match interface

**match interface** <interface-type> <number>  
**no match interface**

Matches the route's interface  
 The no form of the command removes the match clause.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>When a clause contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each match statement.</li> <li>When a route's properties do not equal the statement parameters, the route is evaluated against the next clause in the route map, as determined by sequence number.</li> <li>If all clauses fail to permit or deny the route, the route is denied.</li> </ul> |                   |

## match ip address

**match ip address <prefix-list-name>**

**no match ip address**

Filters according to IPv4 prefix list.

The no form of the command removes this configuration from the route map clause.

## match ip next-hop

**match ip next-hop <value>**

**no match ip next-hop**

Configures a route's entry next-hop match.

The no form of the command removes a route-map's entry next-hop match.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>When a clause contains multiple match commands, the permit or deny filter applies to a route only if its properties are equal to corresponding parameters in each match statement.</li> <li>When a route's properties do not equal the statement parameters, the route is evaluated against the next clause in the route map, as determined by sequence number.</li> <li>If all clauses fail to permit or deny the route, the route is denied.</li> </ul> |                                                 |

## match local-preference

**match local-preference <value>**

**no match local-preference**

Configures a route's entry local-preference match.

The no form of the command removes a route-map's entry local-preference match.

## match metric

**match metric <value>**

**no match metric**

Configures a route's entry metric match.

The no form of the command removes a route-map's entry metric match.

## set as-path prepend

**set as-path prepend** <value<sub>1</sub>> <value<sub>2</sub>> ... <value<sub>n</sub>>

**no set as-path prepend**

Modifies as-path on affected routes

The no form of the command removes the set statement from the route map.

## set metric

**set metric <value>**

**no set metric**

Configures a route's entry metric parameter.

The no form of the command removes a route-map's entry metric setting.

|                           |                                                          |                             |
|---------------------------|----------------------------------------------------------|-----------------------------|
| <b>Syntax Description</b> | value                                                    | Route metric: 1-2147483647. |
| <b>Default</b>            | N/A                                                      |                             |
| <b>Configuration Mode</b> | Config Route Map                                         |                             |
| <b>History</b>            | 3.3.5200                                                 |                             |
| <b>Role</b>               | admin                                                    |                             |
| <b>Example</b>            | switch (config route-map mymap permit 10)# set metric 10 |                             |
| <b>Related Commands</b>   | N/A                                                      |                             |
| <b>Note</b>               |                                                          |                             |

## set origin

**set origin {egp | igp | incomplete}**  
**no set origin**

Configures a route's entry origin parameter.  
 The no form of the command removes a route-map's entry origin setting.

|                           |                                                           |                                                     |
|---------------------------|-----------------------------------------------------------|-----------------------------------------------------|
| <b>Syntax Description</b> | egp                                                       | Set a route's entry origin parameter to external.   |
|                           | igp                                                       | Set a route's entry origin parameter to internal.   |
|                           | incomplete                                                | Set a route's entry origin parameter to incomplete. |
| <b>Default</b>            | N/A                                                       |                                                     |

## 6.5.2 IP Prefix-List

Prefix-list is a list of entries, each of which can match one or more IP prefixes. A prefix-list is usually used to match a specific IP prefix, mostly in relation to IP route destinations.

The prefix is considered to match the list if one of the entries match the prefix; the entry itself can be marked as a “permit” entry or a “deny” entry, which can be used by the matching code to decide if the route is to be accepted or not.

The prefix is matched to the prefix-list entries in the order of the sequence number of the entries in the list.

### 6.5.2.1 Commands

## ip prefix-list

**ip prefix-list** <list-name> [seq <number>] {permit | deny} <ip> [eq <length> | <prefix> [eq <length> | le <length> | ge <length> [le <length>]]]  
**no ip prefix-list** <list-name> [seq <number>]

Creates or updates a prefix-list.  
 The no form of the command deletes a prefix-list or a prefix-list entry

## 6.6 Multicast (IGMP and PIM)

Protocol independent multicast (PIM) is a collection of protocols that deal with efficient delivery of IP multicast (MC) data. Those protocols are published in the series of RFCs and define different ways and aspects of multicast data distribution. PIM protocol family includes PIM dense mode (PIM-DM), PIM sparse mode (PIM-SM), Bidirectional PIM (PIM-BIDIR) and Bootstrap router (BSR) protocol.

PIM builds and maintains multicast routing tables based on the unicast routing information provided by unicast routing tables that can be maintained statically or dynamically by IP routing protocols like OSPF and BGP.

### 6.6.1 Basic PIM-SM

PIM relies on the underlying topology gathering protocols that collect unicast routing information and build multicast routing information base (MRIB). The primary role of MRIB is to determine the next hop for PIM messages. MC data flows along with the reverse path of the PIM control.

MC tree construction contains three phases:

1. Construction of a shared distribution tree. This tree is built around a special designated router (DR) called the rendezvous point (RP).
2. Establishing a native forwarding path from MC sources to the RP
3. Building an optimized MC distribution tree from each MC source to all MC targets bypassing the RP

The first stage of the multicast tree establishment starts when the MC receiver expresses desire to start receiving MC data. It can happen as a result of using one of the L2 protocols like MLD or IGMP, or by static configuration. When such request is received by the last hop router (a designated router) this router starts to build a distribution path from the RP. It starts to send periodic “Join” messages to the nearest PIM neighbor router towards the RP. The next router continues to do the same. Eventually the process converges when Join messages reach RP or a router that has already created that distribution tree. Usually that tree is called a shared tree because it is created for any source for specific MC group G and is noted as (\*,G).

At that stage, MC senders can start sending MC data. The DR next to the MC source extracts the packets from the data flow and tunnels them to the RP. The RP decapsulates the packets and distributes them to all MC receivers along with the share tree.

On the second stage the RP switches from tunneling of multicast packets from MC sources to forwarding native traffic. When the RP identifies that a new MC source started to send packets, it initiates an establishment of a native forwarding path from the DR of that source to itself. For this purpose it starts to send Join messages towards MC source to nearest neighbor to that source according the MRIB. This is a source specific Join and is noted as (S,G). When data path is established up to the DR, the DR switches from tunneling MC packets to their native forwarding, so the RP does not need to decapsulate MC packets anymore, but still continue to distribute the packets along with shared tree.

On the third phase multicast receivers will try to switch from shared tree to source specific tree by creating a direct distribution path from a multicast source. When last hop router of the multicast receiver identifies multicast traffic coming from any multicast source it will start to send Join messages towards the source with purpose to create a direct source specific path to that source. Once such path will be established and Designated router that is attached to the source L2

network will start to distribute the multicast traffic directly bypassing shared tree, the last hop router will detach its receivers from shared tree for that data and will switch to the shortest path tree distribution.

### 6.6.2 Bidirectional PIM

Bidirectional PIM (PIM-BIDIR) is a variant of PIM-SM that builds bidirectional distribution trees that connect multicast senders and receivers. It differs from PIM-SM by eliminating a need to tunnel multicast packets to RP and to keep a state for each (S,G) pair. It also eliminates a need in data driven protocol events. PIM-BIDIR achieves it by defining a new role, Designated Forwarder (DF), and by defining new forwarding rules and keeping all other PIM-SM mechanisms intact.

DF is a PIM enabled router that is the closest router to RP among all PIM routers residing on specific L2 network. It is dynamically elected by all PIM routers on that network. DF is required on each L2 multicast capable network for each RP. DF serves all multicast groups that share the same RP and has following duties:

- It is an only router that is responsible to receive and forward upstream multicast packets on that L2 segment
- It is a router that should collect all Join requests from the routers on that L2 segment
- It is an only router that will distribute downstream multicast packets on that segment.

Once Designated forwarders are elected and forwarding rules are established, PIM routers can start to issue (\*,G) Join messages and build shared distribution trees. When shared tree is created, multicast sources can start to exchange data with receivers and it doesn't require any additional maintenance of the multicast states.

Compared to PIM-SM, in bidirectional PIM:

- Each router will keep only (\*,G) state and not (\*,G) and (S,G) like in PIM-SM
- Multicast traffic from the beginning is forwarded naturally - no need to tunnel data to RP
- Resulting multicast tree is not shortest path optimal and converges around selected Rendezvous point, but is shared among all participants in that multicast group

In BIDIR-PIM, the packet forwarding rules have been improved over PIM-SM, allowing traffic to be passed up the shared tree toward the RP. To avoid multicast packet looping, bidir-PIM introduces a new mechanism called designated forwarder (DF) election, which establishes a loop-free SPT rooted at the RP.

### 6.6.3 Bootstrap Router

For correct operation each PIM router requires a capability to map a multicast group that it needs to serve to a Rendezvous point for that group. This mapping can be done manually or the mapping can be distributed dynamically in the network. BSR protocol serves for this purpose.

This protocol introduces new role in the multicast network – Bootstrap router. That router is responsible to flood multicast group to RP mapping through the multicast routing domain. Bootstrap router is elected dynamically among bootstrap router candidates (C-BSR) and once elected will collect from Rendezvous point candidate (C-RP) mapping information and distribute it in the domain.

Bootstrap activity contains 4 steps. First each C-BSR configured in the network originates floods into the network bootstrap messages that express the router desire to become BSR and also its

BSR priority. Any C-BSR that receives that information and has lower priority will suspend itself, so eventually only one router will send BSR messages and become BSR.

When BSR is elected all RP candidates start to advertise to BSR a list of groups that this RP can serve. On the next step, after BSR learns the group mapping proposals, it forms a final group to RP mapping in the domain and starts to distribute it among PIM routers in the multicast routing domain. When PIM router receives BSR message with the group to RP mapping, it installs that mapping in the router local cache and uses that information to create multicast distribution trees.

## 6.6.4 Configuring Multicast

### Precondition steps:

**Step 1.** Enable IP routing functionality. Run:

```
switch (config)# ip routing
```

**Step 2.** Enable the desired VLAN. Run:

```
switch (config)# vlan 10
```

**Step 3.** Add this VLAN to the desired interface. Run:

```
switch (config)# interface ethernet 1/1
switch (config ethernet 1/1)#switchport access vlan 10
```

**Step 4.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 10
```

**Step 5.** Apply IP address to the VLAN interface. Run:

```
switch (config interface vlan 10)# ip address 10.10.10.10 /24
```

**Step 6.** Enable the interface. Run:

```
switch (config interface vlan 10)# no shutdown
```

### 6.6.4.1 Configuring IGMP

IGMP is enabled when IP multicast is enabled and static multicast or PIM is enabled on the interface.

### 6.6.4.2 Verifying IGMP

**Step 1.** Display a brief IGMP interface status. Run:

```
switch (config)# show ip igmp interface brief
IGMP Interfaces for VRF "default", Count: 1
Interface IP Address IGMP Querier Membership Version
VLAN10 10.10.10.1 10.10.10.1 5 v2
```

**Step 2.** Display detailed IGMP interface status. Run:

```
switch (config)#show ip igmp interface vlan 10
IGMP Interfaces for VRF "default"

VLAN10
Interface status: protocol-up/admin-up/link-up
IP address: 10.10.10.1, IP Subnet: 10.10.10.0/24
Active Querier: 10.10.10.1
Membership count: 5
Route-queue depth: 0
IGMP Version: 2
IGMP query interval: 125 secs, configured value: 125 secs
IGMP max response time: 10 secs, configured value: 10 secs
IGMP startup query interval: 125 secs, configured value: 125 secs
IGMP startup query count: 2
IGMP group timeout: 260 secs, configured value: 260 secs
IGMP querier timeout: 260 secs configured value: 260 secs
IGMP last member mrt: 25 secs configured value: 25
IGMP robustness variable: 2
IGMP interface immediate leave: Disabled
IGMP interface statistics:
General (sent/received):
v1/v2-reports: 0/10
v2-queries: 271/0,v2-leaves: 0/0
v3-queries: 0/0,
v3-reports: 0/0
switch (config)#
```

**Step 3.** Display the list of IGMP groups and their status. Run:

```
switch (config)#show ip igmp groups
IGMP Connected Group Membership for VRF "default", - 2 total entries
Type: S - Static, D - Dynamic, L - Local, T - SSM Translated
Group Address Type Interface Uptime Expires Last
Reporter
226.0.1.0 D vlan10 [0d 00:00:07.46] [0d 00:04:05.08] 10.10.10.2
226.0.1.1 D vlan10 [0d 00:00:07.47] [0d 00:04:05.08] 10.10.10.2
switch (config)#
```

### 6.6.4.3 Configuring PIM

#### Prerequisites:

**Step 1.** If not enabled, enable IP routing. Run:

```
switch (config)# ip routing
```

**Step 2.** Globally enable multicast routing. Run:

```
switch (config)# ip multicast-routing
```

➤ **To configure PIM:**

**Step 1.** Enable PIM. Run:

```
switch (config)# protocol pim
```

**Step 2.** Globally enable Bidirectional PIM (BIDIR mode). Run:

```
switch (config)# no ip pim bidir shutdown
```

## 6.6.5 Commands

### 6.6.5.1 PIM

#### protocol pim

**protocol pim**  
**no protocol pim**

Enables protocol independent multicast (PIM).  
The no form of the command hides all PIM commands and deletes all PIM configurations.

|                           |                                |

| <b>Syntax Description</b> | N/A                            |
| <b>Default</b>            | Disabled                       |
| <b>Configuration Mode</b> | Config                         |
| <b>History</b>            | 3.3.5006                       |
| <b>Role</b>               | admin                          |
| <b>Example</b>            | switch (config) # protocol pim |
| <b>Related Commands</b>   | N/A                            |
| <b>Note</b>               |                                |

## ip pim bidir shutdown

**ip pim bidir shutdown**  
**no ip pim bidir shutdown**

Disables PIM bidir.  
The no form of the command enables PIM bidir.

|                           |                                            |

| <b>Example</b>            | switch (config) # no ip pim bidir shutdown |
| <b>Related Commands</b>   | N/A                                        |
| <b>Note</b>               |                                            |

## ip pim rp-address

**ip pim rp-address <rp-address> [group-list <ip-address> <prefix>] [override]**  
**bidir**  
**no ip pim rp-address <rp-address> [group-list <ip-address> <prefix>]**

Configures a static IP address of a rendezvous point for a multicast group range or adds new multicast range to existing RP.

The no form of the command removes the rendezvous point for a multicast group range or removes all configuration of the RP.

|                           |                                                       |                                                                                     |
|---------------------------|-------------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | rp-address                                            | The static IP address of rendezvous point.                                          |
|                           | ip-address                                            | IP address of the group-range (coupled with the prefix parameter).                  |
|                           | prefix                                                | Network prefix (in the format of /24, or 255.255.255.0 for example) of group range. |
|                           | override                                              | Specifies that this configuration overrides dynamic configuration learned by BSR.   |
|                           | bidir                                                 | Specifies that the group range uses a bidirectional PIM.                            |
| <b>Default</b>            | N/A                                                   |                                                                                     |
| <b>Configuration Mode</b> | Config                                                |                                                                                     |
| <b>History</b>            | 3.3.5006                                              |                                                                                     |
| <b>Role</b>               | admin                                                 |                                                                                     |
| <b>Example</b>            | switch (config) # ip pim rp-address 10.10.10.10 bidir |                                                                                     |
| <b>Related Commands</b>   | N/A                                                   |                                                                                     |
| <b>Note</b>               |                                                       |                                                                                     |

## ip pim bsr-candidate

```
ip pim bsr-candidate {vlan <vlan-id> | loopback <number> | ethernet <port>}
[hash-len <hash-length>] [priority <priority>] [interval <interval>]
no ip pim bsr-candidate {vlan <vlan-id> | loopback <number> | ethernet <port>}
[hash-len <hash-length>] [priority <priority>] [interval <interval>]
```

Configures the switch as a candidate BSR router (C-BSR).  
The no form of the command removes BSR-candidate configuration or restores default parameters values.

|                           |                                                                                                                                                                                    |                                                                              |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------|

---

**Related Commands** ip pim sparse-mode

---

**Note**

- IP PIM sparse-mode must be enabled on the interface.
  - A BSR is a PIM router within the PIM domain through which dynamic RP selection is implemented. The BSR selects RPs from a list of candidate RPs and exchanges bootstrap messages (BSM) with all routers in the domain. The BSR is elected from one of the C-BSRs through an exchange of BSMs. A subset of PIM routers within the domain are configured as candidate Bootstrap routers (C-BSRs). Through the exchange of Bootstrap messages (BSMs), the C-BSRs elect the BSR, which then uses BSMs to inform all domain routers of its status.
  - Command parameters specify the switch's BSR address, the interval between BSM transmissions, hash length used for RP calculations and the priority assigned to the switch when electing a BSR.
  - Entering an ip pim bsr-candidate command replaces any previously configured bsr-candidate command. If the new command does not specify a priority or interval, the previously configured values persist in running-config.

## ip pim bsr-holdtime

**ip pim bsr-holdtime <period>**  
**no ip pim bsr-holdtime**

Configures the timeout period an elected BSR remains valid after receiving a BSM.  
 The no form of the command resets the parameters to their default.

|                           |                                                             |
|---------------------------|-------------------------------------------------------------|
| <b>Syntax Description</b> | period<br>In seconds. Range: 12-1073741823 (1.073 billion). |
| <b>Default</b>            | period = 2*(BSR candidate interval) + 10                    |

| <b>Note</b>               |                                                             |

## ip pim rp-candidate

**ip pim rp-candidate** {vlan <vlan-id> | loopback <number> | ethernet <slot/port>} group-list <ip-address> <prefix> [bidir] [priority <priority>] [interval <interval>]

**no ip pim rp-candidate** {vlan <vlan-id> | loopback <number> | ethernet <slot/port>} group-list <ip-address> <prefix> [bidir] [priority <priority>] [interval <interval>]

Configures the switch as a candidate rendezvous point (C-RP).

The no form of the command removes the ip pim rp-candidate from running-config command for the specified multicast group.

|                           |                                                                                                                                                                                    |                                                                               |

N/A

---

**Note**

- The BSR selects a multicast group's dynamic RP set from the list of C-RPs in the PIM domain. The command specifies the interface (used to derive the RP address), C-RP advertisement interval, and priority rating. The BSR selects the RP set by comparing C-RP priority ratings. The C-RP advertisement interval specifies the period between successive C-RP advertisement message transmissions to the BSR.
  - Running-config supports multiple multicast groups through multiple `ip pim rp-candidate` statements:
  - All commands must specify the same interface. Issuing a command with an interface that differs from existing commands removes all existing commands from running-config.
  - Running-config stores the interval and priority setting in a separate statement that applies to all rp-candidate statements. When a command specifies an interval that differs from the previously configured value, the new value replaces the old value and applies to all configured rp-candidate statements. The default interval value is 60 seconds.
  - When the no commands do not specify a multicast group, all rp-candidate statements are removed from running-config. The `no ip pim rp-candidate interval` commands restore the interval setting to the default value of 60 seconds.
  - When setting a priority, all previous rp-candidates within all interfaces and groups are configured to this priority.
-

## ip pim sparse-mode

**ip pim sparse-mode**  
**no ip pim sparse-mode**

Sets PIM sparse mode on this interface.  
 The no form of the command disables the sparse-mode on the interface and deletes all interfaces configuration.

## ip pim dr-priority

**ip pim dr-priority <priority>**  
**no ip pim dr-priority**

Configures the designated router (DR) priority of PIM Hello messages.  
 The no form of the command resets this parameter to its default.

|                           |                                                                                                                                             |                                                                                  |

| <b>Example</b>            | switch (config interface vlan 10) # ip pim dr-priority 5                                                                                    |                                                                                  |
| <b>Related Commands</b>   | ip pim sparse-mode                                                                                                                          |                                                                                  |
| <b>Note</b>               | The command “ip pim sparse-mode” must be run prior to using this command.                                                                   |                                                                                  |

## ip pim hello-interval

**ip pim hello-interval <interval>**

**no ip pim hello-interval**

Configures PIM Hello interval in milliseconds.

The no form of the command resets this parameter to its default.

| <b>Note</b>               | The command “ip pim sparse-mode” must be run prior to using this command.                                                                   |                                                             |

## ip pim join-prune-interval

**ip pim join-prune-interval <period>**  
**no ip pim join-prune-interval**

Configures the period between Join/Prune messages that the configuration mode interface originates and sends to the upstream RPF neighbor.  
 The no form of the command resets this parameter to its default.

## ip pim border

**ip pim border**  
**no ip pim border**

Configures an interface on an IPv4 PIM border.  
 The no form of the command removes the interface from being a PIM border.

|                           |                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                                         |
| <b>Default</b>            | Disabled                                                                                                                                    |
| <b>Configuration Mode</b> | Config Interface VLAN<br>Config Interface Ethernet configured as a router port<br>Config Interface Port Channel configured as a router port |
| <b>History</b>            | 3.3.5006                                                                                                                                    |
| <b>Role</b>               | admin                                                                                                                                       |
| <b>Example</b>            | switch (config interface vlan 10) # ip pim border                                                                                           |
| <b>Related Commands</b>   |                                                                                                                                             |
| <b>Note</b>               | PIM border blocks PIM control traffic, but sends and receives all multicast traffic.                                                        |

## ip pim bsr-border

**ip pim bsr-border**  
**no ip pim bsr-border**

Prevents the switch from sending bootstrap router messages (BSMs) over the configuration mode interface.

The no form of the command resets the parameter to its default value.

|                           |                                                                                                                                             |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                                         |
| <b>Default</b>            | no pim bsr-border                                                                                                                           |

| <b>Example</b>            | switch (config interface vlan 10) # ip pim bsr-border                                                                                       |
| <b>Related Commands</b>   |                                                                                                                                             |
| <b>Note</b>               |                                                                                                                                             |

## debug ethernet ip pim

**debug ethernet ip pim {all | control-plane | data-path | fail-all | init-shut | management | memory | packet-dump | resources}**  
**no debug ethernet ip pim {all | control-plane | data-path | fail-all | init-shut | management | memory | packet-dump | resources}**

Configures the trace level for PIM.

The no form of the command removes the trace level for PIM.

| <b>Example</b>            | <pre>switch (config) # show ip pim upstream joins Neighbor address: 159.135.45.26 via interface: 159.135.45.34 next message in 43 seconds       Group: 224.0.10.0             Joins:                   22.74.49.25             Prunes:                   No prunes included  switch (config) #</pre> |
| <b>Related Commands</b>   |                                                                                                                                                                                                                                                                                                      |
| <b>Note</b>               | Should contain the following information: neighbor address, interface address, group range, Joins, Prunes.                                                                                                                                                                                           |

## 6.6.5.2 Multicast

### ip multicast-routing

**ip multicast-routing**  
**no ip multicast-routing**

Allows the switch to forward multicast packets.  
The no form of the command disables multicast routing.

|                           |                                       |
|---------------------------|---------------------------------------|
| <b>Syntax Description</b> | N/A                                   |
| <b>Default</b>            | Disabled                              |
| <b>Configuration Mode</b> | Config                                |
| <b>History</b>            | 3.3.5006                              |

| <b>Example</b>            | switch (config)# ip multicast-routing |
| <b>Related Commands</b>   | N/A                                   |
| <b>Note</b>               |                                       |

## ip mroute

**ip mroute** {<ip-addr> <ip-mask> <next-hop>} [pref]  
**no ip mroute** {<ip-addr> <ip-mask>}

Configure multicast reverse path forwarding (RPF) static routes.  
 The no form of the command deletes the static multicast route.

|                           |                                                                                 |                                                                     |

| <b>Related Commands</b>   | N/A                                                                             |                                                                     |
| <b>Note</b>               |                                                                                 |                                                                     |

## ip multicast ttl-threshold

**ip multicast ttl-threshold <ttl-value>**

**no ip multicast ttl-threshold**

Configures the time-to-live (TTL) threshold of packets being forwarded out of an interface.

The no form of the command removes RPF static routes.

|                           |                                                                                                                                             |               |

### 6.6.5.3 IGMP

## ip igmp immediate-leave

**ip igmp immediate-leave**  
**no ip igmp immediate-leave**

Enables the device to remove the group entry from the multicast routing table immediately upon receiving a leave message for the group.  
The no form of the command disables immediate-leave.

## ip igmp last-member-query-count

**ip igmp last-member-query-count <count>**

**no ip igmp last-member-query-count**

Configures the number of query messages the switch sends in response to a group-specific or group-source-specific leave message.

The no form of the command resets this parameter to its default.

| <b>Example</b>            | switch (config interface vlan 10)# ip igmp last-member-query-count 7                                                                        |            |
| <b>Related Commands</b>   | N/A                                                                                                                                         |            |
| <b>Note</b>               | This parameter reflects expected packet loss on a congested network.                                                                        |            |

## ip igmp last-member-query-response-time

**ip igmp last-member-query-response-time <interval>**  
**no ip igmp last-member-query-response-time**

Configures the IGMP last member query response time in seconds.  
 The no form of the command resets this parameter to its default.

## ip igmp static-oif

**ip igmp static-oif <group>**

**no ip igmp static-oif**

Statically binds an IP interface to a multicast group.

The no form of the command deletes the static multicast address from the interface.

|                           |                                                                                                                                             |                       |

| <b>Note</b>               |                                                               |                          |

## debug ethernet ip igmp-l3

**debug ethernet ip igmp-l3 {all | control-plane | data-path | fail-all | init-shut | management | memory | packet-dump | resources}**  
**no debug ethernet ip igmp-l3 {all | control-plane | data-path | fail-all | init-shut | management | memory | packet-dump | resources}**

Configures the trace level for IGMP.

The no form of the command removes the trace level for IGMP.

## 6.7 VRRP

The Virtual Router Redundancy Protocol (VRRP) is a computer networking protocol that provides for automatic assignment of available IP routers to participating hosts. This increases the availability and reliability of routing paths via automatic default gateway selections on an IP sub-network.

The protocol achieves this by creating virtual routers, which are an abstract representation of multiple routers (that is, a master and backup routers, acting as a group). The default gateway of a participating host is assigned to the virtual router instead of a physical router. If the physical router that is routing packets on behalf of the virtual router fails, another physical router is selected to automatically replace it. The physical router that is forwarding packets at any given time is called the master router.

VRRP provides information on the state of a router, not the routes processed and exchanged by that router. Each VRRP instance is limited, in scope, to a single subnet. It does not advertise IP routes beyond that subnet or affect the routing table in any way.

Routers have a priority of between 1-255 and the router with the highest priority becomes the master. The configurable priority value ranges from 1-254, the router which owns the interface IP address has the priority value 255. When a planned withdrawal of a master router is to take place, its priority can be lowered, which means a backup router will preempt the master router status rather than having to wait for the hold time to expire.

### 6.7.1 Load Balancing

To create load balancing between routers participating in the same VR, it is recommended to create 2 (or more) VRs. Each router will be a master in one of the VRs, and a backup to the other VR(s). A group of hosts should be configured with Router 1's virtual address as the default gateway, while the second group should be configured with Router 2's virtual address.

**Figure 35: Common VRRP Configuration with Load Balancing**

## 6.7.2 Configuring VRRP

### ➤ To configure VRRP:

Precondition steps:

**Step 1.** Enable IP routing functionality. Run:

```
switch (config)# ip routing
```

**Step 2.** Enable the desired VLAN. Run:

```
switch (config)# vlan 20
```

The VLAN cannot be the same one configured for the MLAG IPL, if MLAG is used.

**Step 3.** Add this VLAN to the desired interface. Run:

```
switch (config)# interface ethernet 1/1
switch (config ethernet 1/1)# switchport access vlan 20
```

**Step 4.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 20
```

**Step 5.** Apply IP address to the VLAN interface.

On one of the switches, run:

```
switch (config interface vlan 20)# ip address 20.20.20.20 /24
```

On the other switch, run:

```
switch (config interface vlan 20)# ip address 20.20.20.30 /24
```

**Step 6.** Enable the interface. Run:

```
switch (config interface vlan 20)# no shutdown
```

Configure VRRP:

This is the same configuration on both switches

**Step 1.** Enable VRRP protocol globally. Run:

```
switch (config)# protocol vrrp
```

**Step 2.** Create a virtual router group for an IP interface. Up to 255 VRRP IDs are supported. Run:

```
switch (config interface vlan 20)# vrrp 100
```

**Step 3.** Set the VIP address. Run:

```
switch (config interface vlan 20 vrrp 100)# address 20.20.20.40
```

**Step 4.** Influence the election of the master in the VR cluster make sure that the priority of the desired master is the highest. Note that the higher IP address is selected in case the priority of the routers in the VR are the same. Select the priority. Run:

```
switch (config interface vlan 20 vrrp 100)# priority 200
```

**Step 5.** The advertisement interval should be the same for all the routers within the VR. Modify the interval. Run:

```
switch (config interface vlan 20 vrrp 100)# advertisement-interval 2
```

**Step 6.** The authentication text should be the same for all the routers within the VR. Configure the authentication text. Run:

```
switch (config interface vlan 20 vrrp 100)# authentication text my-password
```

**Step 7.** Use the preempt command to enable a high-priority backup virtual router to preempt the low-priority master virtual router. Run:

```
switch (config interface vlan 20 vrrp 100)# preempt
```

**Step 8.** Disable VRRP. Run:

```
switch (config interface vlan 20 vrrp 100)# shutdown
```

The configuration will not be deleted, only the VRRP state machine will be stopped.

### 6.7.3 Verifying VRRP

**Step 1.** Display VRRP brief status. Run:

```
switch(config)# show vrrp
Interface VR Pri Time Pre State VR IP addr

Vlan20 1 200 2s Y Init 20.20.20.20
...
switch(config)#
```

**Step 2.** Display VRRP detailed status. Run:

```
switch (config)# show vrrp detail

VRRP Admin State : Enabled

Vlan20 - Group 1 (IPv4)

Instance Admin State : Enabled
State : Backup
Virtual IP Address : 20.20.20.40
Priority : 200
Advertisement interval (sec) : 2
Preemption : Enabled
Virtual MAC address : AA:BB:CC:DD:EE:FF
switch (config)#
```

**Step 3.** Display VRRP statistic counters. Run:

```
switch (config)# show vrrp statistics
Ethernet1/5 - Group 1 (IPv4)
Invalid packets: 0
Too short: 0
Transitions to Master 6
Total received: 155
Bad TTL: 0
Failed authentication: 0
Unknown authentication: 0
Conflicting authentication: 0
Conflicting Advertise time: 0
Conflicting Addresses: 0
Received with zero priority: 3
Sent with zero priority: 3
switch (config)#
```

## 6.7.4 Commands

### protocol vrrp

**protocol vrrp**  
**no protocol vrrp**

Enables VRRP globally and unhides VRRP related commands.  
The no form of the command deletes all the VRRP configuration and hides VRRP related commands.

| <b>Note</b>               |                                |

## vrrp

**vrrp <number>**  
**no vrrp <number>**

Creates a virtual router group on this interface and enters a new configuration mode. The no form of the command deletes the VRRP instance and the related configuration.

| <b>Note</b>               | Maximum of 10 VRRP instances are supported.                                      |                                         |

## address

**address** <ip-address> [secondary]  
**no address** [<ip-address> [secondary]]

Sets virtual router IP address (primary and secondary).  
 The no form of the command deletes the IP address from the VRRP interface.

Therefore, set all the protocol parameters initially and only then set the ip-address.</li><li>• There are up to 10 IP addresses associated with the VRRP instance. One primary and up to 10 secondary ip-addresses.</li><li>• If the configured IP address is the same as the interface IP address, this switch automatically owns the IP address (priority 255).</li></ul> |                                                |

## shutdown

**shutdown**  
**no shutdown**

Disables the virtual router.  
The no form of the command enables the virtual router (stops the VRRP state machine).

|                           |                                    |

## priority

**priority <level>**

**no priority**

Sets the priority of the virtual router.

The no form of the command resets the priority to its default.

|                           |                                                                                                                                                                                                                                                                                                     |                                                    |

## preempt

**preempt**  
**no preempt**

Sets virtual router preemption mode.  
The no form of the command disables the virtual router preemption.

|                           |                                                                                              |
|---------------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                          |
| <b>Default</b>            | Enabled (preempt)                                                                            |
| <b>Configuration Mode</b> | Config VRRP Interface                                                                        |
| <b>History</b>            | 3.3.4500                                                                                     |
| <b>Role</b>               | admin                                                                                        |
| <b>Example</b>            | switch (config vrrp 100)# preempt                                                            |
| <b>Related Commands</b>   |                                                                                              |
| <b>Note</b>               | To set this router as backup for the current virtual router master, preempt must be enabled. |

## authentication text

**authentication text <password>**

**no authentication text**

Sets virtual router authentication password and enables authentication.  
The no form of the command disables the authentication mechanism.

|                           |                                                          |                                                                                                          |
|---------------------------|----------------------------------------------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | password                                                 | The virtual router authentication password. The password string must be up to 8 alphanumeric characters. |
| <b>Default</b>            | Disabled                                                 |                                                                                                          |

| <b>Note</b>               |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |                                                                   |

## 6.8 MAGP

Multi-active gateway protocol (MAGP) is aimed to solve the default gateway problem when a host is connected to a set of switch routers (SRs) via MLAG.

The network functionality in that case requires that each SR is an active default gateway router to the host, thus reducing hops between the SRs and directly forwarding IP traffic to the L3 cloud regardless which SR traffic comes through.

Designated traffic, such as ping to the MAGP interface is not supported. One of the two switches will be able to ping, so a ping from one switch can be done.

### 6.8.1 MAGP Configuration

Prerequisite steps:

**Step 1.** Enable IP routing functionality. Run:

```
switch (config)# ip routing
```

**Step 2.** Enable the desired VLAN. Run:

```
switch (config)# vlan 20
switch (config vlan 20)#
```

The VLAN cannot be the same one configured for the MLAG IPL, if MLAG is used.

**Step 3.** Add this VLAN to the desired interface. Run:

```
switch (config)# interface ethernet 1/1
switch (config interface ethernet 1/1)# switchport access vlan 20
```

**Step 4.** Create a VLAN interface. Run:

```
switch (config)# interface vlan 20
switch (config interface vlan 20)#
```

**Step 5.** Set an IP address to the VLAN interface. Run:

```
switch (config interface vlan 20)# ip address 11.11.11.11 /8
```

**Step 6.** Enable the interface. Run:

```
switch (config interface vlan 20)# no shutdown
```

#### ➤ **To configure MAGP:**

**Step 1.** Enable MAGP protocol globally. Run:

```
switch (config)# protocol magp
```

**Step 2.** Create a virtual router group for an IP interface. Run:

```
switch (config interface vlan 20)# magp 100
```

Up to 255 MAGP IDs are supported.

**Step 3.** Set a virtual router primary IP address. Run:

```
switch (config interface vlan 20 magp 100)# ip virtual-router address 11.11.11.254
```

The IP address must be in the same subnet of the VLAN interface. This IP address is the default gateway for this MAGP instance. This should become the default gateway configured on the hosts connected to the relevant MLAG.

**Step 4.** Set a virtual router primary MAC address. Run:

```
switch (config interface vlan 20 magp 100)# ip virtual-router mac-address
AA:BB:CC:DD:EE:FF
```

➤ **To verify the MAGP configuration, run:**

```
switch (config)# show magp 1
MAGP 1
 Interface vlan:1
 MAGP state:Master
 MAGP virtual IP: 11.11.11.254
 MAGP virtual MAC: AA:BB:CC:DD:EE:FF
switch (config)#
```

This output is to be expected in both MAGP switches.

## 6.8.2 Commands

### protocol magp

**protocol magp**  
**no protocol magp**

Enables MAGP globally and unhides MAGP commands.  
The no form of the command deletes all the MAGP configuration and hides MAGP commands.

| <b>Example</b>            | switch (config)# protocol magp<br>switch (config)# |
| <b>Related Commands</b>   |                                                    |
| <b>Note</b>               | IP routing must be enabled to enable MAGP.         |

## magp

**magp <instance>**  
**no magp <instance>**

Creates an MAGP instance on this interface and enters a new configuration mode.  
 The no form of the command deletes the MAGP instance.

|                           |                                                                                                                                                                                                                         |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• Only one MAGP instance can be created on an interface</li> <li>• Different interfaces cannot share an MAGP instance</li> <li>• MAGP and VRRP are mutually exclusive</li> </ul> |

## shutdown

**shutdown**  
**no shutdown**

Enables MAGP instance.  
 The no form of the command disables the MAGP instance.

|                           |                                                                                                      |

## ip virtual-router address

**ip virtual-router address <ip-address>**

**no ip virtual-router address**

Sets MAGP virtual IP address.

The no form of the command resets this parameter to its default.

|                           |                                                                                                                                      |                                |

| <b>Note</b>               | The MAGP virtual IP address must be different from the interface IP address                                                          |                                |

## ip virtual-router mac-address

**ip virtual-router mac-address <mac-address>**

**no ip virtual-router mac-address**

Sets MAGP virtual MAC address.

The no form of the command resets the MAC address to its default.

## 6.9 DHCP Relay

DHCP Relay is not supported on SX10xx-xxxR and SX60xx-xxxR systems.

Since Dynamic Host Configuration Protocol must work correctly even before DHCP clients have been configured, the DHCP server and DHCP client need to be connected to the same network.

In larger networks, this is not always practical because each network link contains one or more DHCP relay agents. These DHCP relay agents receive messages from DHCP clients and forward them to DHCP servers thus extending the reach of the DHCP beyond the local network.

## 6.9.1 Commands

### ip dhcp relay address

**ip dhcp relay address <ip-address>**  
**no ip dhcp relay address <ip-address>**

Configures IP address of the DHCP server to forward DHCP requests.  
 The no form of the command deletes the DHCP server IP address.

## ip dhcp relay information option

**ip dhcp relay information option**  
**no ip dhcp relay information option**

Enables the DHCP relay agent to insert option 82 info on the packets.  
The no form of the command removes option 82 from the packets.

|                           |                                                                       |

| <b>Note</b>               |                                                                       |

## ip dhcp relay always-on

**ip dhcp relay always-on**  
**no ip dhcp relay always-on**

Broadcasts DHCP requests to all interfaces with the DHCP relay agent.  
 The no form of the command disables the “always-on” mode.

|                           |                                                                                                                                                                                                                                                                                                                        |

### 6.9.1.1 Interface

## ip dhcp relay information option circuit-id

**ip dhcp relay information option circuit-id <label>**  
**no ip dhcp relay information option circuit-id**

Specifies the content of tags that the switch attaches to DHCP requests before they are forwarded.

The no form of the command removes the label assigned.

# 7 InfiniBand Switching

## 7.1 Node Name

### 7.1.1 Commands

#### ib nodename

**ib nodename <guid> name <name>**  
**no ib nodename <guid>**

Maps between GUID and node name.

## 7.3 Interface

### 7.3.1 Transceiver Information

MLNX-OS offers the option of viewing the transceiver information of a module or cable connected to a specific interface. The information is a set of read-only parameters burned onto the EEPROM of the transceiver by the manufacture. The parameters include identifier (connector type), cable type, speed and additional inventory attributes.

➤ **To display transceiver information of a specific interface, run:**

```
switch (config) # show interfaces ib 1/36 transceiver
Slot 1 port 36 state
 identifier : QSFP+
 cable/ module type : Passive copper, unequalized
 infiniband speeds : SDR , DDR , QDR , FDR
 vendor : Mellanox
 cable length : 2m
 part number : MC2207130-0A1
 revision : A3
 serial number : MT1324VS02215

switch (config) #
```

The indicated cable length is rounded up to the nearest natural number.

### 7.3.2 High Power Transceivers

Mellanox switch systems offer high power transceiver (e.g. LR4) support in the following ports:

- SX6036 – ports 1, 3, 33, 35
- SX6012/SX6710/SX6720 – all ports
- SB7700 – all ports
- TX6000/TX6100 – all uplink ports

If a high power transceiver (e.g. LR4) is inserted to a port that does not support it, the link does not go up, and the following warning message is displayed: “Warning: High power transceiver is not supported” when the command “show interfaces ib” is run.

### 7.3.3 Commands

## interface ib

**interface ib [internal] {<inf> | <inf-range>}**

Enters the InfiniBand interface configuration mode.

|                           |                                                                          |                                                                                                                                                                                                                          |

## shutdown

**shutdown**  
**no shutdown**

Disables the interface.  
The no form of the command enables the interface.

## speed

**speed <port speed>**

Sets the speed of the interface.

|                           |                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                           |

## op-vls

### **op-vls <value>**

Sets the operational VLs of the interface.

The no form of the command sets the operational VLs to its default value.

| <b>Note</b>               | <p>If a high power transceiver (e.g. LR4) is inserted to a port that does not support it, the link will not go up, and the following warning message is displayed: “Warning: High power transceiver is not supported” when the command “show interfaces ib” is run. For more information, please refer to <a href="#">Section 7.3.2, “High Power Transceivers,” on page 999</a>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                                                                                                          |

## show interfaces ib status

**show interfaces ib [[internal] leaf-ports] [<inf>] status**

Displays the status, speed and negotiation mode of the specified interface.

## show interfaces ib transceiver

**show interfaces ib [<inf>] transceiver**

Displays the transceiver info.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 7.4 Subnet Manager (SM)

The InfiniBand Subnet Manager (SM) is a centralized entity running in the switch. The SM discovers and configures all the InfiniBand fabric devices to enable traffic flow between those devices.

The SM applies network traffic related configurations such as Quality of Service (QoS), routing, and partitioning of the fabric devices. You can view and configure the Subnet Parameters (SM) via the CLI/WebUI menu. The embedded SM on the MLNX-OS can be used to manage fabrics up to 648 nodes.

### 7.4.1 Enabling Subnet Manager

The SM is used to discover and configure all the InfiniBand fabric devices to enable traffic flow between those devices.

➤ **To enable Subnet Manager:**

**Step 1.** Enable - `ib smnode <name> enable`

Enables the Subnet Manager. Subnet Manager is disabled by default.

**Step 2.** [Optional] Priority - `ib smnode <name> sm-priority <priority>`

Sets the Subnet Manager priority on the system. Subnet Manager's default priority is 0.

Changing the host name closes the SM manager session. To restart SM please run `ib smnode <new hostname> enable`.

### 7.4.2 Partitions

Partitioning enforces isolation among systems sharing an InfiniBand fabric. Partitioning is not related to boundaries established by subnets, switches, or routers. Rather, a partition describes a set of end nodes within the fabric that may communicate. Each port of an end node is a member of at least one partition and may be a member of multiple partitions. A partition manager (part of the SM) assigns partition keys (PKEYs) to each channel adapter port. Each PKEY represents a partition. Reception of an invalid PKEY causes the packet to be discarded. Switches and routers may optionally be used to enforce partitioning. In this case the partition manager programs the switch or router with PKEY information and when the switch or router detects a packet with an invalid PKEY, it discards the packet.

Fabric administration can assign certain Service Levels (SLs) for particular partitions. This allows the SM to isolate traffic flows between those partitions, and even if both partitions operate at the same QoS level, each partition can be guaranteed its fair share of bandwidth regardless of whether nodes in other partitions misbehave or are over subscribed.

The switch enables the configuration of partitions in an InfiniBand fabric.

The default partition is created by the SM unconditionally (whether it was defined or not).

#### 7.4.2.1 Relationship with ib0 Interface

IP interface “ib0” is running under the default PKEY (0x7fff) and can be used for inband management connectivity to the system.

### 7.4.2.2 Configuring Partition

The partitions configuration is applicable and to be used only when the SM is enabled and running on the system.

➤ **To configure a partition:**

**Step 1.** Create a partition. Run:

```
switch (config) # ib partition my-partition pkey 0x7ff2
```

**Step 2.** Enter partition configuration mode. Run:

```
switch (config) # partition my-partition
switch (config partition name my-partition) #
```

**Step 3.** Add partition members. Run:

```
switch (config partition my-partition) # member all
```

**Step 4.** Verify the partition configuration. Run:

```
switch (config partition my-partition) # show ib partition
Default
 PKey = 0x7FFF
 defmember = full
 ipoib = yes
members
 GUID='ALL' member='full'
my-partition
 PKey = 0x7ff2
members
 GUID='ALL' member='default'
switch (config partition name my-partition) #
```

### 7.4.3 Adaptive Routing

Adaptive routing (AR) allows optimizing data traffic flow. The InfiniBand protocol uses multiple paths between any two points. Thus, when unexpected traffic patterns cause some paths to be overloaded, AR can automatically move traffic to less congested paths according to the current temporal state of the network.

The embedded SM over the switch does not support configuring adaptive routing. To use this option in the fabric please use an external SM.

AR support is enabled by default on system profile “ib-single-switch”. To disable AR run the command system profile ib-no-adaptive-routing-single-switch.

The AR option needs to be enabled in the SM for it to take affect.

## 7.4.4 Commands

### 7.4.4.1 Subnet Manager (SM)

#### **ib sm**

**ib sm**

**no ib sm**

Enables the SM on this node.

The no form of the command disables the SM on this node.

| <b>Example</b>            | switch (config) # ib sm<br>switch (config) # |
| <b>Related Commands</b>   | show ib sm                                   |
| <b>Note</b>               |                                              |

## ib sm accum-log-file

**ib sm accum-log-file**  
**no ib sm accum-log-file**

Adds SM log entries at the end of the current log.  
 The no form of the command overwrites SM log file on every restart.

|                           |                                                                                                                      |
|---------------------------|----------------------------------------------------------------------------------------------------------------------|

| <b>Note</b>               |                                                                                                                      |

## ib sm allow-both-pkeys

**ib sm allow-both-pkeys**  
**no ib sm allow-both-pkeys**

Enables having both full and limited membership on the same partition.  
 The no form of the command disables having both full and limited membership on the same partition.

|                           |                                                               |

## ib sm babbling-policy

**ib sm babbling-policy**  
**no ib sm babbling-policy**

Enables the SM to disable babbling ports (i.e., generating frequent traps).  
 The no form of the command disables the SM babbling policy.

|                           |                                                                                                                                                               |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                                                           |
| <b>Default</b>            | disable                                                                                                                                                       |
| <b>Configuration Mode</b> | Config                                                                                                                                                        |
| <b>History</b>            | 3.1.0000                                                                                                                                                      |
| <b>Role</b>               | admin                                                                                                                                                         |
| <b>Example</b>            | <pre>switch (config) # no ib sm babbling-policy switch (config) # show ib sm babbling-policy disable switch (config) #</pre>                                  |
| <b>Related Commands</b>   | show ib sm babbling-policy                                                                                                                                    |
| <b>Note</b>               | In case the babbling policy is enabled, and decides to close a babbling interface (one which sends 129,130,131 traps, for example), the SM disables the port. |

## ib sm connect-roots

**ib sm connect-roots**  
**no ib sm connect-roots**

Forces the routing engine to make connectivity between root switches.  
 The no form of the command disables logical LID path between root switches.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Example</b>            | <pre>switch (config) # ib sm connect-roots switch (config) # show ib sm connect-roots true switch (config) #</pre>                                                                                                                                                                                                                                                                                                                              |
| <b>Related Commands</b>   | show ib sm connect-roots                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Note</b>               | <ul style="list-style-type: none"> <li>• This command is relevant only for 'updn' and 'ftree' algorithm (refer to 'ib sm routing-engines' command)</li> <li>• This option enforces routing engines (up/down and fat-tree) to make connectivity between root switches and in this way to be fully IBA complaint. This may violate the "deadlock-free" status of the algorithm. Hence, it is recommended to use the command carefully.</li> </ul> |

## ib sm enable-quirks

**ib sm enable-quirks**  
**no ib sm enable-quirks**

Enables the SM to use high risk features and handle hardware workarounds.  
 The no form of the command disables the SM from using high risk features and hardware workarounds.

## ib sm force-log-flush

**ib sm force-log-flush**  
**no ib sm force-log-flush**

Forces every log message generated to be flushed.  
 The no form of the command does not force a flush after every log write.

## ib sm guid2lid-cache

**ib sm guid2lid-cache**  
**no ib sm guid2lid-cache**

Allows SM to use cached GUID-to-lid mapping data. When enabled, the SM honors the cached GUID-to-lid mapping information if:

- It exists
- It is valid
- sm\_reassign\_lids is disabled

The no form of the command disallows use of cached GUID-to-lid mapping data.

## ib sm honor-partitions

**ib sm honor-partitions**  
**no ib sm honor-partitions**

Sets the no\_partition\_enforcement flag to 0. This setting controls global support for partitioning in the subnet.  
 The no form of the command disables subnet partition support.

## ib sm leafhoq-lifetime

**ib sm leafhoq-lifetime <time>**

Sets the maximum time a frame can wait at the head of a switch-to-CA\_or\_Router port queue before it is dropped.

|                           |                                                                                                                                        |                                                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | time                                                                                                                                   | The time is 4.096 uS * 2time. The range of time is 0 to 20. A time of 20 means infinite, and the default value is 18 which translates to about 1 second. |
| <b>Default</b>            | 0x10 (about 268 mS)                                                                                                                    |                                                                                                                                                          |
| <b>Configuration Mode</b> | Config                                                                                                                                 |                                                                                                                                                          |
| <b>History</b>            | 3.1.0000                                                                                                                               |                                                                                                                                                          |

## ib sm lmc

### ib sm lmc <mask>

Sets the LID Mask Control (LMC) value to be used on this subnet.

|                           |                                                                                                 |                       |
|---------------------------|-------------------------------------------------------------------------------------------------|-----------------------|
| <b>Syntax Description</b> | mask                                                                                            | Valid values are 0-7. |
| <b>Default</b>            | The default value is 0, which means that every port has exactly one unique LID.                 |                       |
| <b>Configuration Mode</b> | Config                                                                                          |                       |
| <b>History</b>            | 3.1.0000                                                                                        |                       |
| <b>Role</b>               | admin                                                                                           |                       |
| <b>Example</b>            | <pre>switch (config) # ib sm lmc 7 switch (config) # show ib sm lmc 0x7 switch (config) #</pre> |                       |
| <b>Related Commands</b>   | show ib sm lmc                                                                                  |                       |
| <b>Note</b>               |                                                                                                 |                       |

## ib sm lmc-esp0

**ib sm lmc-esp0**  
**no ib sm lmc-esp0**

Sets the LMC for the subnet to be used for Enhanced Switch Port 0.

|                           |                                                       |
|---------------------------|-------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                   |
| <b>Default</b>            | disable                                               |
| <b>Configuration Mode</b> | Config                                                |
| <b>History</b>            | 3.1.0000                                              |

| <b>Related Commands</b>   | show ib sm lmc-esp0                                   |
| <b>Note</b>               |                                                       |

## ib sm log-flags

**ib sm log-flags [all] [debug] [error] [frames] [funcs] [info] [none] [routing] [verbose]**

**no ib sm log-flags**

Controls what messages the SM logs.

The no form of the command indicates to the SM not to run on this node.

|                           |                                                                                                                                                                                                        |                                                                                     |

| <b>Related Commands</b>   | show ib sm msgfifo-timeout                                                                                                                                                            |                  |
| <b>Note</b>               | If there is more than one message in the SA queue, and it has been there longer than time milliseconds, all additional incoming requests are immediately replied to with BUSY status. |                  |

## ib sm multicast

**ib sm multicast**  
**no ib sm multicast**

Enables the SM to support multicasts on the fabric.  
 The no form of the command disables the SM from supporting multicasts on the fabric.

|                           |                                                                                                            |

## ib sm overrun-trigger

**ib sm overrun-trigger <count>**

Enables SMA to generate standard InfiniBand trap number 130 when the number of local buffer overrun errors equals the count value, and the port's SMA supports traps.

|                           |                                                                                                                       |               |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------|---------------|
| <b>Syntax Description</b> | count                                                                                                                 | Range: 0-255. |
| <b>Default</b>            | 8                                                                                                                     |               |
| <b>Configuration Mode</b> | Config                                                                                                                |               |
| <b>History</b>            | 3.1.0000                                                                                                              |               |
| <b>Role</b>               | admin                                                                                                                 |               |
| <b>Example</b>            | <pre>switch (config) # ib sm overrun-trigger 3 switch (config) # show ib sm overrun-trigger 3 switch (config) #</pre> |               |
| <b>Related Commands</b>   | show ib sm overrun-trigger                                                                                            |               |
| <b>Note</b>               | Refer to the <i>InfiniBand Architecture Specification V1 r1.2.1</i> , section 14.2.5.1 table 131: Traps.              |               |

## ib sm packet-life-time

### ib sm packet-life-time <time>

Sets the maximum time a frame can live in a switch.

|                           |                                                                                                                                        |                                                                                                                          |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | time                                                                                                                                   | The time is 4.096 uS * 2*<time>. The rang is: 0-20. A time of 20 means infinite. The value 0x14 disables this mechanism. |
| <b>Default</b>            | 0x12 (about 1 second)                                                                                                                  |                                                                                                                          |
| <b>Configuration Mode</b> | Config                                                                                                                                 |                                                                                                                          |
| <b>History</b>            | 3.1.0000                                                                                                                               |                                                                                                                          |

| <b>Role</b>               | admin                                                                                                                                 |                     |
| <b>Example</b>            | <pre>switch (config) # ib sm polling-retries 8 switch (config) # show ib sm polling-retries 8 switch (config) #</pre>                 |                     |
| <b>Related Commands</b>   | show ib sm polling-retries                                                                                                            |                     |
| <b>Note</b>               | The time between when the active SM fails and the time this SM declares it dead is: (sm_sminfo_polling_timeout * value) milliseconds. |                     |

## ib sm port-prof-switch

**ib sm port-prof-switch**  
**no ib sm port-prof-switch**

Enables the counting of adapters, routers, and switches routed through links.  
 The no form of the command disables the counting of adapters, routers, and switches routed through links.

|                           |                                                                                                                        |

## ib sm reassign-lids

**ib sm reassign-lids**  
**no ib sm reassign-lids**

Controls the ability of the SM to reassign LIDs to nodes it finds already configured with a valid LID.

The no form of the command disables the SM from reassigning LIDs to nodes it finds already configured with a valid LID.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## ib sm root-guid

**ib sm root-guid <guid>**  
**no ib sm root-guid <guid>**

Adds a root GUID for the SM.  
 The no form of the command removes the GUID from the root GUID list.

|                           |                                                                                                                            |                                               |

| <b>Role</b>               | admin                                                                                                                      |                                               |
| <b>Example</b>            | switch (config)# ib sm root-guid aa:bb:00:11:22:33:44:55<br>switch (config) #                                              |                                               |
| <b>Related Commands</b>   | show ib sm routing-engines                                                                                                 |                                               |
| <b>Note</b>               | The list of root GUIDs are relevant when IB SM is running on the switch, and the routing algorithm is up-down or fat-tree. |                                               |

## ib sm routing-engines

**ib sm routing-engines [dor] [file] [ftree] [lash] [minhop] [none] [updn]**  
**no ib sm routing-engines**

Sets the routing engine of the SM.

The no form of the command sets the routing engine to be “none”. The default SM routing engine is used.

| <b>Role</b>               | admin                                                                                                                                                         |                                                            |
| <b>Example</b>            | <pre>switch (config) # ib sm routing-engines none switch (config) # show ib sm routing-engines none none switch (config) #</pre>                              |                                                            |
| <b>Related Commands</b>   | show ib sm routing-engines                                                                                                                                    |                                                            |
| <b>Note</b>               | Multiple routing engines can be specified separated by# commas so that specific ordering of routing algorithms will be tried if earlier routing engines fail. |                                                            |

## ib sm sa-key

### ib sm sa-key <SA\_Key>

Sets the SA\_Key 64-bit value used by SA to qualify that a query is “trusted”.

|                           |                                                                                                                                                                 |         |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| <b>Syntax Description</b> | SA Key                                                                                                                                                          | 64 bit. |
| <b>Default</b>            | 00:00:00:00:00:00:00:01                                                                                                                                         |         |
| <b>Configuration Mode</b> | config                                                                                                                                                          |         |
| <b>History</b>            | 3.1.0000                                                                                                                                                        |         |
| <b>Role</b>               | admin                                                                                                                                                           |         |
| <b>Example</b>            | <pre>switch (config) # ib sm sa-key 5 switch (config) # show ib sm sa-key 00:00:00:00:00:00:00:05 switch (config) #</pre>                                       |         |
| <b>Related Commands</b>   | show ib sm sa-key                                                                                                                                               |         |
| <b>Note</b>               | OpenSM version 3.2.1 and lower used the default value of “1” in host byte order. You may need to change this value to inter-operate with older subnet managers. |         |

## ib sm single-thread

**ib sm single-thread**  
**no ib sm single-thread**

Enables the Subnet Manager to use a single thread to service all requests.  
 The no form of the command enables SA to use multiple service threads.

|                           |                                                                                                                    |
|---------------------------|--------------------------------------------------------------------------------------------------------------------|

| <b>Note</b>               |                                                                                                                    |

## ib sm sm-inactive

**ib sm sm-inactive**  
**no ib sm sm-inactive**

Configures the SM to start in the “inactive” SM state. This option can be used to run a standalone system without the SM/SA function.

The no form of the command configures the SM to start in “init” SM state.

|                           |                                                                                                                  |

| <b>History</b>            | 3.1.0000                                                                                                                                                        |        |
| <b>Role</b>               | admin                                                                                                                                                           |        |
| <b>Example</b>            | <pre>switch (config) # ib sm sm-key 00:00:00:00:00:00:00:05 switch (config) # show ib sm sm-key 00:00:00:00:00:00:00:05 switch (config) #</pre>                 |        |
| <b>Related Commands</b>   | show ib sm sm-key                                                                                                                                               |        |
| <b>Note</b>               | OpenSM version 3.2.1 and lower used the default value of “1” in host byte order. You may need to change this value to inter-operate with older subnet managers. |        |

## ib sm sm-priority

**ib sm sm-priority <priority>**

Prioritizes the desired SM compared to other SMs on the fabric.

|                           |                                                                                                                 |                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------|
| <b>Syntax Description</b> | priority                                                                                                        | Priority 0 is the least important, 15 the most important. |
| <b>Default</b>            | 0                                                                                                               |                                                           |
| <b>Configuration Mode</b> | Config                                                                                                          |                                                           |
| <b>History</b>            | 3.1.0000                                                                                                        |                                                           |
| <b>Role</b>               | admin                                                                                                           |                                                           |
| <b>Example</b>            | <pre>switch (config) # ib sm sm-priority 1 switch (config) # show ib sm sm-priority 1 switch (config) #</pre>   |                                                           |
| <b>Related Commands</b>   | show ib sm sm-priority                                                                                          |                                                           |
| <b>Note</b>               | If two or more active SMs have the same highest priority, the one with the lowest port GUID manages the fabric. |                                                           |

## ib sm sm-sl

**ib sm sm-sl <sm-sl>**

Sets the SM service level for SM/SA communication.

|                           |                                                                                                     |       |
|---------------------------|-----------------------------------------------------------------------------------------------------|-------|
| <b>Syntax Description</b> | sm-sl                                                                                               | 0-15. |
| <b>Default</b>            | 0                                                                                                   |       |
| <b>Configuration Mode</b> | Config                                                                                              |       |
| <b>History</b>            | 3.1.0000                                                                                            |       |
| <b>Role</b>               | admin                                                                                               |       |
| <b>Example</b>            | <pre>switch (config) # ib sm sm-sl 10 switch (config) # show ib sm sm-sl 10 switch (config) #</pre> |       |
| <b>Related Commands</b>   | show ib sm sm-sl                                                                                    |       |
| <b>Note</b>               | Selects the SL that is used for MADs.                                                               |       |

## ib sm sminfo-poll-time

**ib sm sminfo-poll-time <time>**

This variable controls the timeout between two polls of an active subnet manager.

|                           |                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | time<br>In milliseconds.                                                                                                             |
| <b>Default</b>            | 10 seconds                                                                                                                           |
| <b>Configuration Mode</b> | Config                                                                                                                               |
| <b>History</b>            | 3.1.0000                                                                                                                             |
| <b>Role</b>               | admin                                                                                                                                |
| <b>Example</b>            | switch (config) # ib sm sminfo-poll-time 15<br>switch (config) # show ib sm sminfo-poll-time<br>15 milliseconds<br>switch (config) # |
| <b>Related Commands</b>   | show ib sm sminfo-poll-time                                                                                                          |
| <b>Note</b>               |                                                                                                                                      |

## ib sm subnet-prefix

### ib sm subnet-prefix <prefix>

Sets the SM “Subnet Prefix” used to create scope qualifiers for all elements managed by the SM.

|                           |                                                                                                                                                               |        |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|--------|
| <b>Syntax Description</b> | prefix                                                                                                                                                        | 64 bit |
| <b>Default</b>            | FE:80:00:00:00:00:00:00                                                                                                                                       |        |
| <b>Configuration Mode</b> | Config                                                                                                                                                        |        |
| <b>History</b>            | 3.1.0000                                                                                                                                                      |        |
| <b>Role</b>               | admin                                                                                                                                                         |        |
| <b>Example</b>            | <pre>switch (config) # ib sm subnet-prefix ff:ff:ff:ff:ff:ff:ff:00 switch (config) # show ib sm subnet-prefix FF:FF:FF:FF:FF:FF:FF:00 switch (config) #</pre> |        |
| <b>Related Commands</b>   | show ib sm subnet-prefix                                                                                                                                      |        |
| <b>Note</b>               | The default value is also the InfiniBand default for a locally administered subnet.                                                                           |        |

## ib sm subnet-timeout

### **ib sm subnet-timeout <time>**

Sets the global per-port subnet timeout value (PortInfo:SubnetTimeOut). This value also controls the maximum trap frequency in which no traps are allowed to be sent faster than the subnet\_timeout value.

|                           |                                                                                                                                      |                                                                                                                                                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | time                                                                                                                                 | The actual timeout is $4.096 \text{ uS} * 2^{*} \text{<time>}$ . The range of time is 0-31 for this parameter which supports 32 discrete time values between 4 uS and about 2.4 hours. |
| <b>Default</b>            | 0x12 (About 1 second)                                                                                                                |                                                                                                                                                                                        |
| <b>Configuration Mode</b> | Config                                                                                                                               |                                                                                                                                                                                        |
| <b>History</b>            | 3.1.0000                                                                                                                             |                                                                                                                                                                                        |

| <b>Example</b>            | <pre>switch (config) # ib sm subnet-timeout 5 switch (config) # show ib sm subnet-timeout 0x5 (About 131 uS) switch (config) #</pre> |                                                                                                                                                                                        |
| <b>Related Commands</b>   | show ib sm subnet-timeout                                                                                                            |                                                                                                                                                                                        |
| <b>Note</b>               | If the SMA generates a sequence of traps, the interval between successive traps should not be smaller than <time>.                   |                                                                                                                                                                                        |

## ib sm sweep-interval

**ib sm sweep-interval <time>**

**no ib sm sweep-interval**

Specifies the time between subnet sweeps.  
The no form of the command disables periodic sweeps.

|                           |                                                                                                                               |                                                   |

## ib sm sweep-on-trap

**ib sm sweep-on-trap**  
**no ib sm sweep-on-trap**

Enables every TRAP received by the SM to initiate a heavy sweep in addition to the processing required by the TRAP.

The no form of the command enables SM to use a combination of light and heavy sweeps based on the type of TRAP and other internal states.

|                           |                                                                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                               |
| <b>Default</b>            | enable                                                                                                                            |
| <b>Configuration Mode</b> | Config                                                                                                                            |
| <b>History</b>            | 3.1.0000                                                                                                                          |
| <b>Role</b>               | admin                                                                                                                             |
| <b>Example</b>            | <pre>switch (config) # ib sm sweep-on-trap switch (config) # show ib sm sweep-on-trap enable switch (config) #</pre>              |
| <b>Related Commands</b>   | show ib sm sweep-on-trap                                                                                                          |
| <b>Note</b>               | More than 10 successive identical TRAPs disable the automatic sweep behavior until at least one different TRAP has been received. |

## ib sm transaction-retries

**ib sm transaction-retries <transaction-retries-count>**

Sets the maximum retries for failed transactions.

|                           |                                                                                                                               |                     |

| <b>Note</b>               |                                                                                                                               |                     |

## ib sm use-heavy-sweeps

**ib sm use-heavy-sweeps**  
**no ib sm use-heavy-sweeps**

Turns every fabric sweep to a heavy sweep.  
 The no form of the command enables the SM to use a combination of light and heavy sweeps.

|                           |                                                                                                                          |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------|

| <b>Note</b>               |                                                                                                                          |

## ib sm use-ucast-cache

**ib sm use-ucast-cache**  
**no ib sm use-ucast-cache**

Enables the SM to use cached routine data (LMC=0 only).  
 The no form of the command disables the SM to use cached routine data.

|                           |                                                                                                                        |

| <b>Syntax Description</b> | N/A                                                                                                                    |
| <b>Default</b>            | Disable                                                                                                                |
| <b>Configuration Mode</b> | Config                                                                                                                 |
| <b>History</b>            | 3.1.0000                                                                                                               |
| <b>Role</b>               | admin                                                                                                                  |
| <b>Example</b>            | <pre>switch (config) # ib sm use-ucast-cache switch (config) # show ib sm use-ucast-cache true switch (config) #</pre> |
| <b>Related Commands</b>   | show ib sm use-ucast-cache                                                                                             |
| <b>Note</b>               |                                                                                                                        |

## ib sm vl-stalls

### ib sm vl-stalls <count>

Sets the number of sequential frame drops that cause a switch-to-switch port to enter the VLStalled state.

|                           |                                                                                                             |       |
|---------------------------|-------------------------------------------------------------------------------------------------------------|-------|
| <b>Syntax Description</b> | count                                                                                                       | 1-255 |
| <b>Default</b>            | 7                                                                                                           |       |
| <b>Configuration Mode</b> | Config                                                                                                      |       |
| <b>History</b>            | 3.1.0000                                                                                                    |       |
| <b>Role</b>               | admin                                                                                                       |       |
| <b>Example</b>            | <pre>switch (config) # ib sm vl-stalls 10 switch (config) # show ib sm vl-stalls 10 switch (config) #</pre> |       |
| <b>Related Commands</b>   | show ib sm vl-stalls                                                                                        |       |
| <b>Note</b>               |                                                                                                             |       |

## show ib sm

### show ib sm

Displays the SM admin state.

|                           |                                                             |
|---------------------------|-------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                         |
| <b>Default</b>            | N/A                                                         |
| <b>Configuration Mode</b> | Config                                                      |
| <b>History</b>            | 3.1.0000                                                    |
| <b>Role</b>               | admin                                                       |
| <b>Example</b>            | switch (config) # show ib sm<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm                                                       |
| <b>Note</b>               |                                                             |

## show ib sm accum-log-file

### show ib sm accum-log-file

Displays the accum-log-file configuration.

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                        |
| <b>Default</b>            | N/A                                                                        |
| <b>Configuration Mode</b> | Config                                                                     |
| <b>History</b>            | 3.1.0000                                                                   |
| <b>Role</b>               | admin                                                                      |
| <b>Example</b>            | switch (config) # show ib sm accum-log-file<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm accum-log-file                                                       |
| <b>Note</b>               |                                                                            |

## show ib sm babbling-policy

### show ib sm babbling-policy

Displays the ability of the SM to disable babbling ports (i.e., generating frequent traps).

|                           |                                                                              |
|---------------------------|------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                          |
| <b>Default</b>            | N/A                                                                          |
| <b>Configuration Mode</b> | Config                                                                       |
| <b>History</b>            | 3.1.0000                                                                     |
| <b>Role</b>               | admin                                                                        |
| <b>Example</b>            | switch (config) # show ib sm babbling-policy<br>disable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm babbling-policy                                                        |
| <b>Note</b>               |                                                                              |

## show ib sm connect-roots

### show ib sm connect-roots

Displays the IBA compliant multi-stage switch directive.

|                           |                                                                         |
|---------------------------|-------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                     |
| <b>Default</b>            | N/A                                                                     |
| <b>Configuration Mode</b> | Config                                                                  |
| <b>History</b>            | 3.1.0000                                                                |
| <b>Role</b>               | admin                                                                   |
| <b>Example</b>            | switch (config) # show ib sm connect-roots<br>true<br>switch (config) # |
| <b>Related Commands</b>   | ib sm connect-roots                                                     |
| <b>Note</b>               |                                                                         |

## show ib sm enable-quirks

### show ib sm enable-quirks

Displays if the SM uses high risk features and handles HW workarounds.

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                        |
| <b>Default</b>            | N/A                                                                        |
| <b>Configuration Mode</b> | Config                                                                     |
| <b>History</b>            | 3.1.0000                                                                   |
| <b>Role</b>               | admin                                                                      |
| <b>Example</b>            | switch (config) # show ib sm enable-quirks<br>disable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm enable-quirks                                                        |
| <b>Note</b>               |                                                                            |

## show ib sm exit-on-fatal

### show ib sm exit-on-fatal

Displays if the SM exits upon a fatal error.

|                           |                                                                           |
|---------------------------|---------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                       |
| <b>Default</b>            | N/A                                                                       |
| <b>Configuration Mode</b> | Config                                                                    |
| <b>History</b>            | 3.1.0000                                                                  |
| <b>Role</b>               | admin                                                                     |
| <b>Example</b>            | switch (config) # show ib sm exit-on-fatal<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm exit-on-fatal                                                       |
| <b>Note</b>               |                                                                           |

## show ib sm fdr10

### show ib sm fdr10

Displays the status of the SM use of FDR10.

|                           |                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                               |
| <b>Default</b>            | N/A                                                                               |
| <b>Configuration Mode</b> | Config                                                                            |
| <b>History</b>            | 3.1.0000                                                                          |
| <b>Role</b>               | admin                                                                             |
| <b>Example</b>            | switch (config) # show ib sm fdr10<br>SM use of fdr10 is off<br>switch (config) # |
| <b>Related Commands</b>   |                                                                                   |
| <b>Note</b>               |                                                                                   |

## show ib sm force-link-speed

### show ib sm force-link-speed

Displays SM behavior for PortInfo:LinkSpeedEnabled parameter on switch ports.

|                           |                                                                                                                            |
|---------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                        |
| <b>Default</b>            | N/A                                                                                                                        |
| <b>Configuration Mode</b> | Config                                                                                                                     |

| <b>Example</b>            | <pre>switch (config) # show ib sm force-link-speed-ext 31 (Default: set to PortInfo:LinkSpeedExtSupported) switch (config) #</pre> |
| <b>Related Commands</b>   |                                                                                                                                    |
| <b>Note</b>               |                                                                                                                                    |

## show ib sm force-log-flush

### show ib sm force-log-flush

Displays if every log message generated forces the log to be flushed.

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                         |
| <b>Default</b>            | N/A                                                                         |
| <b>Configuration Mode</b> | Config                                                                      |
| <b>History</b>            | 3.1.0000                                                                    |
| <b>Role</b>               | admin                                                                       |
| <b>Example</b>            | switch (config) # show ib sm force-log-flush<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm force-log-flush                                                       |
| <b>Note</b>               |                                                                             |

## show ib sm guid2lid-cache

### show ib sm guid2lid-cache

Displays whether or not the SM honors the cached GUID-to-LID mapping information.

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                         |
| <b>Default</b>            | N/A                                                                         |
| <b>Configuration Mode</b> | Config                                                                      |
| <b>History</b>            | 3.1.0000                                                                    |
| <b>Role</b>               | admin                                                                       |
| <b>Example</b>            | switch (config) # show ib sm guid2lid-cache<br>disable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm guid2-lid-cache                                                       |
| <b>Note</b>               |                                                                             |

## show ib sm honor-partitions

### show ib sm honor-partitions

Displays the partition enforcement settings in the subnet.

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                           |
| <b>Default</b>            | N/A                                                                           |
| <b>Configuration Mode</b> | Config                                                                        |
| <b>History</b>            | 3.1.0000                                                                      |
| <b>Role</b>               | admin                                                                         |
| <b>Example</b>            | switch (config) # show ib sm honor-partitions<br>disable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm honor-partitions                                                        |
| <b>Note</b>               |                                                                               |

## show ib sm hoq-lifetime

### show ib sm hoq-lifetime

Displays the maximum time a frame can wait at the head of a switch-to-switch port queue before it is dropped.

|                           |                                                                                         |
|---------------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                     |
| <b>Default</b>            | N/A                                                                                     |
| <b>Configuration Mode</b> | Config                                                                                  |
| <b>History</b>            | 3.1.0000                                                                                |
| <b>Role</b>               | admin                                                                                   |
| <b>Example</b>            | switch (config) # show ib sm hoq-lifetime<br>0x12 (About 1 second)<br>switch (config) # |
| <b>Related Commands</b>   | ib sm hoq-lifetime                                                                      |
| <b>Note</b>               |                                                                                         |

## show ib sm ignore-other-sm

### show ib sm ignore-other-sm

Displays if the rules governing SM elections and attempt to manage the fabric on the node are ignored by the SM.

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                         |
| <b>Default</b>            | N/A                                                                         |
| <b>Configuration Mode</b> | Config                                                                      |
| <b>History</b>            | 3.1.0000                                                                    |
| <b>Role</b>               | admin                                                                       |
| <b>Example</b>            | switch (config) # show ib sm ignore-other-sm<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm ignore-other-sm                                                       |
| <b>Note</b>               |                                                                             |

## show ib sm ipv6-nsm

### show ib sm ipv6-nsm

Displays the consolidation of IPv6 Solicited Node Multicast (SNM) group join requests.

|                           |                                                                      |
|---------------------------|----------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                  |
| <b>Default</b>            | N/A                                                                  |
| <b>Configuration Mode</b> | Config                                                               |
| <b>History</b>            | 3.1.0000                                                             |
| <b>Role</b>               | admin                                                                |
| <b>Example</b>            | switch (config) # show ib sm ipv6-nsm<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm ipv6-nsm                                                       |
| <b>Note</b>               |                                                                      |

## show ib sm lash

**show ib sm lash {do-mesh-analysis | start-vl}**

Display 'lash' routing method parameters.

|                           |                                                                                   |
|---------------------------|-----------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                               |
| <b>Default</b>            | N/A                                                                               |
| <b>Configuration Mode</b> | Config                                                                            |
| <b>History</b>            | 3.1.0000                                                                          |
| <b>Role</b>               | admin                                                                             |
| <b>Example</b>            | switch (config) # show ib sm lash do-mesh-analysis<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm lash                                                                        |
| <b>Note</b>               |                                                                                   |

## show ib sm leafhoq-lifetime

### show ib sm leafhoq-lifetime

Displays the maximum time a frame can wait at the head of a switch-to-CA\_or\_Router port queue before it is dropped.

|                           |                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                       |
| <b>Default</b>            | N/A                                                                                       |

| <b>Syntax Description</b> | N/A                                                                         |
| <b>Default</b>            | N/A                                                                         |
| <b>Configuration Mode</b> | Config                                                                      |
| <b>History</b>            | 3.1.0000                                                                    |
| <b>Role</b>               | admin                                                                       |
| <b>Example</b>            | switch (config) # show ib sm log-max-size<br>50 MBytes<br>switch (config) # |
| <b>Related Commands</b>   | is sm log-max-size                                                          |
| <b>Note</b>               |                                                                             |

## show ib sm m-key

### show ib sm m-key

Display MKey value.

|                           |                                                                      |
|---------------------------|----------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                  |
| <b>Default</b>            | N/A                                                                  |
| <b>Configuration Mode</b> | Config                                                               |
| <b>History</b>            | 3.1.0000                                                             |
| <b>Role</b>               | admin                                                                |
| <b>Example</b>            | switch (config) # show ib sm m-key<br>50 MBytes<br>switch (config) # |
| <b>Related Commands</b>   | ib sm m-key                                                          |
| <b>Note</b>               |                                                                      |

## show ib sm max-op-vls

### show ib sm max-op-vls

Displays the maximum number of VLs supported on this subnet.

|                           |                                                                    |
|---------------------------|--------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                |
| <b>Default</b>            | N/A                                                                |
| <b>Configuration Mode</b> | Config                                                             |
| <b>History</b>            | 3.1.0000                                                           |
| <b>Role</b>               | admin                                                              |
| <b>Example</b>            | switch (config) # show ib sm max-op-vls<br>15<br>switch (config) # |
| <b>Related Commands</b>   | ib sm max-op-vls                                                   |
| <b>Note</b>               |                                                                    |

## show ib sm max-ports

### show ib sm max-ports

Displays the number of CA ports SM can manage

|                           |                                                                     |
|---------------------------|---------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                 |
| <b>Default</b>            | N/A                                                                 |
| <b>Configuration Mode</b> | Config                                                              |
| <b>History</b>            | 3.1.0000                                                            |
| <b>Role</b>               | admin                                                               |
| <b>Example</b>            | switch (config) # show ib sm max-ports<br>2048<br>switch (config) # |
| <b>Related Commands</b>   | ib sm max-ports                                                     |
| <b>Note</b>               |                                                                     |

## show ib sm max-reply-time

### show ib sm max-reply-time

Displays the maximum time in milliseconds that the SM will wait for a reply before the transaction times out.

|                           |                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                  |
| <b>Default</b>            | N/A                                                                                  |
| <b>Configuration Mode</b> | Config                                                                               |
| <b>History</b>            | 3.1.0000                                                                             |
| <b>Role</b>               | admin                                                                                |
| <b>Example</b>            | switch (config) # show ib sm max-reply-time<br>200 milliseconds<br>switch (config) # |
| <b>Related Commands</b>   | ib sm max-reply-time                                                                 |
| <b>Note</b>               |                                                                                      |

## show ib sm max-reverse-hops

### show ib sm max-reverse-hops

Displays max hops IO node to top switch

|                           |                                                                              |
|---------------------------|------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                          |
| <b>Default</b>            | N/A                                                                          |
| <b>Configuration Mode</b> | Config                                                                       |
| <b>History</b>            | 3.1.0000                                                                     |
| <b>Role</b>               | admin                                                                        |
| <b>Example</b>            | switch (config) # show ib sm max-reverse-hops<br>0 hops<br>switch (config) # |
| <b>Related Commands</b>   | ib sm max-reverse-hops                                                       |
| <b>Note</b>               |                                                                              |

## show ib sm max-smpps-timeout

### show ib sm max-smpps-timeout

Displays timeout for SMPs between max\_wire\_smpps & max\_wire\_smpps2.

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                           |
| <b>Default</b>            | N/A                                                                           |
| <b>Configuration Mode</b> | Config                                                                        |
| <b>History</b>            | 3.1.0000                                                                      |
| <b>Role</b>               | admin                                                                         |
| <b>Example</b>            | switch (config) # show ib sm max-smpps-timeout<br>600000<br>switch (config) # |
| <b>Related Commands</b>   |                                                                               |
| <b>Note</b>               |                                                                               |

## show ib sm max-wire-smpps

### show ib sm max-wire-smpps

Displays the maximal number of MADs the SM will have outstanding at one time to count.

|                           |                                                                       |
|---------------------------|-----------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                   |
| <b>Default</b>            | N/A                                                                   |
| <b>Configuration Mode</b> | Config                                                                |
| <b>History</b>            | 3.1.0000                                                              |
| <b>Role</b>               | admin                                                                 |
| <b>Example</b>            | switch (config) # show ib sm max-wire-smpps<br>8<br>switch (config) # |
| <b>Related Commands</b>   | ib sm max-wire-smpps                                                  |
| <b>Note</b>               |                                                                       |

## show ib sm max-wire-smpps2

### show ib sm max-wire-smpps2

Displays maximal SM timeout based packets allowed to be outstanding.

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                    |
| <b>Default</b>            | N/A                                                                    |
| <b>Configuration Mode</b> | Config                                                                 |
| <b>History</b>            | 3.1.0000                                                               |
| <b>Role</b>               | admin                                                                  |
| <b>Example</b>            | switch (config) # show ib sm max-wire-smpps2<br>4<br>switch (config) # |
| <b>Related Commands</b>   |                                                                        |
| <b>Note</b>               |                                                                        |

## show ib sm mkey-lease

### show ib sm mkey-lease

Display MKey period in seconds.

|                           |                                                                                |
|---------------------------|--------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                            |
| <b>Default</b>            | N/A                                                                            |
| <b>Configuration Mode</b> | Config                                                                         |
| <b>History</b>            | 3.1.0000                                                                       |
| <b>Role</b>               | admin                                                                          |
| <b>Example</b>            | switch (config) # show ib sm mkey-lease<br>0 (No timeout)<br>switch (config) # |
| <b>Related Commands</b>   | ib sm mkey-lease                                                               |
| <b>Note</b>               |                                                                                |

## show ib sm msgfifo-timeout

### show ib sm msgfifo-timeout

Displays the elapsed time in milliseconds before a frame at the head of Subnet Agent queue causes an immediate BUSY state.

|                           |                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                 |
| <b>Default</b>            | N/A                                                                                 |
| <b>Configuration Mode</b> | Config                                                                              |
| <b>History</b>            | 3.1.0000                                                                            |
| <b>Role</b>               | admin                                                                               |
| <b>Example</b>            | switch (config) # show ib sm msgfifo-timeout<br>10.000 seconds<br>switch (config) # |
| <b>Related Commands</b>   | ib sm msgfifo-timeout                                                               |
| <b>Note</b>               |                                                                                     |

## show ib sm multicast

### show ib sm multicast

Displays whether the SM supports multicast on the fabric.

|                           |                                                                       |
|---------------------------|-----------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                   |
| <b>Default</b>            | N/A                                                                   |
| <b>Configuration Mode</b> | Config                                                                |
| <b>History</b>            | 3.1.0000                                                              |
| <b>Role</b>               | admin                                                                 |
| <b>Example</b>            | switch (config) # show ib sm multicast<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm multicast                                                       |
| <b>Note</b>               |                                                                       |

## show ib sm no-client-rereg

### show ib sm no-client-rereg

Displays client re-registration admin state.

|                           |                                                                             |
|---------------------------|-----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                         |
| <b>Default</b>            | N/A                                                                         |
| <b>Configuration Mode</b> | Config                                                                      |
| <b>History</b>            | 3.1.0000                                                                    |
| <b>Role</b>               | admin                                                                       |
| <b>Example</b>            | switch (config) # show ib sm no-client-rereg<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib no-client-rereg                                                          |
| <b>Note</b>               |                                                                             |

## show ib sm overrun-trigger

### show ib sm overrun-trigger

Displays count of local buffer overrun errors for Infiniband trap 130

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                    |
| <b>Default</b>            | N/A                                                                    |
| <b>Configuration Mode</b> | Config                                                                 |
| <b>History</b>            | 3.1.0000                                                               |
| <b>Role</b>               | admin                                                                  |
| <b>Example</b>            | switch (config) # show ib sm overrun-trigger<br>3<br>switch (config) # |
| <b>Related Commands</b>   | ib sm overrun-trigger                                                  |
| <b>Note</b>               |                                                                        |

## show ib sm packet-life-time

### show ib sm packet-life-time

Displays the maximum time a frame can live in a switch.

|                           |                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                   |
| <b>Default</b>            | N/A                                                                                   |
| <b>Configuration Mode</b> | Config                                                                                |
| <b>History</b>            | 3.1.0000                                                                              |
| <b>Role</b>               | admin                                                                                 |
| <b>Example</b>            | switch (config) # show ib sm packet-life-time<br>0x14 (Infinite)<br>switch (config) # |
| <b>Related Commands</b>   | ib sm packet-life-time                                                                |
| <b>Note</b>               |                                                                                       |

## show ib sm phy-err-trigger

### show ib sm phy-err-trigger

Displays the number of local link integrity errors and the port's SMA supports traps.

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                    |
| <b>Default</b>            | N/A                                                                    |
| <b>Configuration Mode</b> | Config                                                                 |
| <b>History</b>            | 3.1.0000                                                               |
| <b>Role</b>               | admin                                                                  |
| <b>Example</b>            | switch (config) # show ib sm phy-err-trigger<br>5<br>switch (config) # |
| <b>Related Commands</b>   | ib sm phy-err-trigger                                                  |
| <b>Note</b>               |                                                                        |

## show ib sm polling-retries

### show ib sm polling-retries

Displays the number of consecutive times an active SM must fail to respond before it is declared dead.

|                           |                                                                        |
|---------------------------|------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                    |
| <b>Default</b>            | N/A                                                                    |
| <b>Configuration Mode</b> | Config                                                                 |
| <b>History</b>            | 3.1.0000                                                               |
| <b>Role</b>               | admin                                                                  |
| <b>Example</b>            | switch (config) # show ib sm polling-retries<br>8<br>switch (config) # |
| <b>Related Commands</b>   | ib sm polling-retries                                                  |
| <b>Note</b>               |                                                                        |

## show ib sm port-prof-switch

### show ib sm port-prof-switch

Displays whether or not the counting of adapters, routers, and switches through the links is being done.

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                        |
| <b>Default</b>            | N/A                                                                        |
| <b>Configuration Mode</b> | Config                                                                     |
| <b>History</b>            | 3.1.0000                                                                   |
| <b>Role</b>               | admin                                                                      |
| <b>Example</b>            | switch (config) # show ib sm port-prof-switch<br>true<br>switch (config) # |
| <b>Related Commands</b>   | ib sm port-prof-switch                                                     |
| <b>Note</b>               |                                                                            |

## show ib sm reassign-lids

### show ib sm reassign-lids

Displays the ability of the SM to reassign LIDs to nodes it finds already configured with a valid LID.

|                           |                                                                           |
|---------------------------|---------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                       |
| <b>Default</b>            | N/A                                                                       |
| <b>Configuration Mode</b> | Config                                                                    |
| <b>History</b>            | 3.1.0000                                                                  |
| <b>Role</b>               | admin                                                                     |
| <b>Example</b>            | switch (config) # show ib sm reassign-lids<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm reassign-lids                                                       |
| <b>Note</b>               |                                                                           |

## show ib sm root-guid

### show ib sm root-guid

Displays the configured root GUIDs for the SM.

|                           |                                                                                                                                      |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                                  |
| <b>Default</b>            | N/A                                                                                                                                  |
| <b>Configuration Mode</b> | Config                                                                                                                               |
| <b>History</b>            | 3.1.0000                                                                                                                             |
| <b>Role</b>               | admin                                                                                                                                |
| <b>Example</b>            | <pre>switch (config)# show ib sm root-guid AA:00:11:22:33:44:55 AA:00:11:22:33:44:56 AA:00:11:22:33:44:57 ... switch (config)#</pre> |
| <b>Related Commands</b>   | ib sm routing-engine                                                                                                                 |
| <b>Note</b>               | The list of root GUIDs are relevant when IB SM is running on the switch, and the routing algorithm is up-down or fat-tree.           |

## show ib sm routing-engines

### show ib sm routing-engines

Displays an ordered list of routing engines

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                      |
| <b>Default</b>            | N/A                                                                      |
| <b>Configuration Mode</b> | Config                                                                   |
| <b>History</b>            | 3.1.0000                                                                 |
| <b>Role</b>               | admin                                                                    |
| <b>Example</b>            | switch (config) # show ib sm routing-engine<br>none<br>switch (config) # |
| <b>Related Commands</b>   | ib sm routing-engine                                                     |
| <b>Note</b>               |                                                                          |

## show ib sm routing-info

### show ib sm routing-info

Displays current routing engine information.

|                           |                                                                                                 |
|---------------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                             |
| <b>Default</b>            | N/A                                                                                             |
| <b>Configuration Mode</b> | Config                                                                                          |
| <b>History</b>            | 3.1.0000                                                                                        |
| <b>Role</b>               | admin                                                                                           |
| <b>Example</b>            | switch (config) # show ib sm routing-info<br>Current routing engine minhop<br>switch (config) # |
| <b>Related Commands</b>   |                                                                                                 |
| <b>Note</b>               |                                                                                                 |

## show ib sm sa-key

### show ib sm sa-key

Displays the SM sa-key value used by SA to qualify that a query is “trusted”.

|                           |                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                 |
| <b>Default</b>            | N/A                                                                                 |
| <b>Configuration Mode</b> | Config                                                                              |
| <b>History</b>            | 3.1.0000                                                                            |
| <b>Role</b>               | admin                                                                               |
| <b>Example</b>            | switch (config) # show ib sm sa-key<br>00:00:00:00:00:00:00:05<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sa-key                                                                        |
| <b>Note</b>               |                                                                                     |

## show ib sm single-thread

### show ib sm single-thread

Displays if the SM uses a single thread to service all requests.

|                           |                                                                           |
|---------------------------|---------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                       |
| <b>Default</b>            | N/A                                                                       |
| <b>Configuration Mode</b> | Config                                                                    |
| <b>History</b>            | 3.1.0000                                                                  |
| <b>Role</b>               | admin                                                                     |
| <b>Example</b>            | switch (config) # show ib sm single-thread<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm single-thread                                                       |
| <b>Note</b>               |                                                                           |

## show ib sm sm-inactive

### show ib sm sm-inactive

Displays whether or not the SM starts in “inactive” rather than “init” SM state.

|                           |                                                                         |
|---------------------------|-------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                     |
| <b>Default</b>            | N/A                                                                     |
| <b>Configuration Mode</b> | Config                                                                  |
| <b>History</b>            | 3.1.0000                                                                |
| <b>Role</b>               | admin                                                                   |
| <b>Example</b>            | switch (config) # show ib sm sm-inactive<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sm-inactive                                                       |
| <b>Note</b>               |                                                                         |

## show ib sm sm-key

### show ib sm sm-key

Displays the SM 64-bit SM\_Key.

|                           |                                                                                     |
|---------------------------|-------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                 |
| <b>Default</b>            | N/A                                                                                 |
| <b>Configuration Mode</b> | Config                                                                              |
| <b>History</b>            | 3.1.0000                                                                            |
| <b>Role</b>               | admin                                                                               |
| <b>Example</b>            | switch (config) # show ib sm sm-key<br>00:00:00:00:00:00:00:05<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sm-key                                                                        |
| <b>Note</b>               |                                                                                     |

## show ib sm sm-priority

### show ib sm sm-priority

Displays the importance of this SM compared to other SMs on the fabric.

|                           |                                                                                                                                                                             |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                                                                         |
| <b>Default</b>            | N/A                                                                                                                                                                         |
| <b>Configuration Mode</b> | Config                                                                                                                                                                      |
| <b>History</b>            | 3.1.0000                                                                                                                                                                    |
| <b>Role</b>               | admin                                                                                                                                                                       |
| <b>Example</b>            | switch (config) # show ib sm sm-priority<br>1<br>switch (config) #                                                                                                          |
| <b>Related Commands</b>   | ib sm sm-priority                                                                                                                                                           |
| <b>Note</b>               | Priority 0 is the least important, 15 the most important. If 2 or more active SMs have the same highest priority, the one with the lowest port GUID will manage the fabric. |

## show ib sm sm-sl

### show ib sm sm-sl

Display SL used for SM/SA communication

|                           |                                                              |
|---------------------------|--------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                          |
| <b>Default</b>            | N/A                                                          |
| <b>Configuration Mode</b> | Config                                                       |
| <b>History</b>            | 3.1.0000                                                     |

| <b>Example</b>            | switch (config) # show ib sm sm-sl<br>1<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sm-sl                                                  |
| <b>Note</b>               |                                                              |

## show ib sm sminfo-poll-time

### show ib sm sminfo-poll-time

Displays the timeout in milliseconds between two polls of an active SM.

|                           |                                                                                       |
|---------------------------|---------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                   |
| <b>Default</b>            | N/A                                                                                   |
| <b>Configuration Mode</b> | Config                                                                                |
| <b>History</b>            | 3.1.0000                                                                              |
| <b>Role</b>               | admin                                                                                 |
| <b>Example</b>            | switch (config) # show ib sm sminfo-poll-time<br>15 milliseconds<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sminfo-poll-time                                                                |
| <b>Note</b>               |                                                                                       |

## show ib sm subnet-prefix

### show ib sm subnet-prefix

Displays the SM “Subnet Prefix” used to create scope qualifiers for all elements managed by the SM.

|                           |                                                                                            |
|---------------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                        |
| <b>Default</b>            | N/A                                                                                        |
| <b>Configuration Mode</b> | Config                                                                                     |
| <b>History</b>            | 3.1.0000                                                                                   |
| <b>Role</b>               | admin                                                                                      |
| <b>Example</b>            | switch (config) # show ib sm subnet-prefix<br>FF:FF:FF:FF:FF:FF:FF:00<br>switch (config) # |
| <b>Related Commands</b>   | ib sm subnet-prefix                                                                        |
| <b>Note</b>               |                                                                                            |

## show ib sm subnet-timeout

### show ib sm subnet-timeout

Displays the global per-port subnet timeout value (PortInfo:SubnetTimeOut). This value also controls the maximum trap frequency in which no traps are allowed to be sent faster than the subnet\_timeout value. The time is  $4.096 \text{ uS} * 2^{\text{time}}$ .

|                           |                                                                                        |
|---------------------------|----------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                    |
| <b>Default</b>            | N/A                                                                                    |
| <b>Configuration Mode</b> | Config                                                                                 |
| <b>History</b>            | 3.1.0000                                                                               |
| <b>Role</b>               | admin                                                                                  |
| <b>Example</b>            | switch (config) # show ib sm subnet-timeout<br>0x5 (About 131 uS)<br>switch (config) # |
| <b>Related Commands</b>   | ib sm subnet-timeout                                                                   |
| <b>Note</b>               |                                                                                        |

## show ib sm sweep-interval

### show ib sm sweep-interval

Displays the time in seconds between subnet sweeps.

|                           |                                                                                |
|---------------------------|--------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                            |
| <b>Default</b>            | N/A                                                                            |
| <b>Configuration Mode</b> | Config                                                                         |
| <b>History</b>            | 3.1.0000                                                                       |
| <b>Role</b>               | admin                                                                          |
| <b>Example</b>            | switch (config) # show ib sm sweep-interval<br>20 seconds<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sweep-interval                                                           |
| <b>Note</b>               |                                                                                |

## show ib sm sweep-on-trap

### show ib sm sweep-on-trap

Displays whether or not a heavy sweep is initiated by the TRAP received by the SM.

|                           |                                                                           |
|---------------------------|---------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                       |
| <b>Default</b>            | N/A                                                                       |
| <b>Configuration Mode</b> | Config                                                                    |
| <b>History</b>            | 3.1.0000                                                                  |
| <b>Role</b>               | admin                                                                     |
| <b>Example</b>            | switch (config) # show ib sm sweep-on-trap<br>enable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm sweep-on-trap                                                       |
| <b>Note</b>               |                                                                           |

## show ib sm transaction-retries

### show ib sm transaction-retries

Displays maximum retries before failing a transaction

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                        |
| <b>Default</b>            | N/A                                                                        |
| <b>Configuration Mode</b> | Config                                                                     |
| <b>History</b>            | 3.1.0000                                                                   |
| <b>Role</b>               | admin                                                                      |
| <b>Example</b>            | switch (config) # show ib sm transaction-retries<br>3<br>switch (config) # |
| <b>Related Commands</b>   | ib sm transaction-retries                                                  |
| <b>Note</b>               |                                                                            |

## show ib sm use-heavy-sweeps

### show ib sm use-heavy-sweeps

Displays SM requirement to always use heavy sweeps.

|                           |                                                                               |
|---------------------------|-------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                           |
| <b>Default</b>            | N/A                                                                           |
| <b>Configuration Mode</b> | Config                                                                        |
| <b>History</b>            | 3.1.0000                                                                      |
| <b>Role</b>               | admin                                                                         |
| <b>Example</b>            | switch (config) # show ib sm use-heavy-sweeps<br>disable<br>switch (config) # |
| <b>Related Commands</b>   | ib sm use-heavy-sweeps                                                        |
| <b>Note</b>               |                                                                               |

## show ib sm use-ucast-cache

### show ib sm use-ucast-cache

Displays if the SM uses cached routine data.

|                           |                                                                            |
|---------------------------|----------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                        |
| <b>Default</b>            | N/A                                                                        |
| <b>Configuration Mode</b> | Config                                                                     |
| <b>History</b>            | 3.1.0000                                                                   |
| <b>Role</b>               | admin                                                                      |
| <b>Example</b>            | switch (config) # show ib sm use-ucast-cache<br>false<br>switch (config) # |
| <b>Related Commands</b>   | ib sm user-ucase-cache                                                     |
| <b>Note</b>               |                                                                            |

## show ib sm version

### show ib sm version

Displays the open SM version that is currently running.

|                           |                                                                          |
|---------------------------|--------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                      |
| <b>Default</b>            | N/A                                                                      |
| <b>Configuration Mode</b> | Config                                                                   |
| <b>History</b>            | 3.2.3000                                                                 |
| <b>Role</b>               | admin                                                                    |
| <b>Example</b>            | switch (config) # show ib sm version<br>OpenSM3.3.7<br>switch (config) # |
| <b>Related Commands</b>   |                                                                          |
| <b>Note</b>               |                                                                          |

## show ib sm vl-stalls

### show ib sm use-vl-stalls

Displays the number of sequential frame drops that cause a switch-to-switch port to enter the VLStalled state.

|                           |                                                                  |
|---------------------------|------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                              |

### 7.4.4.2 Partition (SM)

## ib partition

**ib partition** <partition-name> [pkey <pkey number>]  
**no ib partition** <partition-name>

Enters the context of the partition specified.  
 The no form of the command deletes the partition.

|                           |                                                                                         |                                                          |

## pkey

**pkey <number>**  
**no pkey <number>**

Specifies PKEY number for this partition.  
 The no form of the command removes the PKEY configuration from partitions.conf file.

|                           |                                                                                                                                                      |              |

| <b>Note</b>               | PKEY must be unique.                                                                                                                                 |              |

## defmember

**defmember <type>**

**no defmember**

Sets the default membership for port GUID list.

The no form of the command set the defmember configuration to default (it will not appear in the partitions.conf file).

| <b>Note</b>               | This parameter can be overwritten for specific GUID, using the “member” command.                                                                              |                                                                                                                                             |

## member

**member** {<guid> | all | self} [type <member-type>]

**no member** {<guid> | all | self} [type]

Adds static members to partition.

The no form of the command will remove the static member from the partition (it will not appear in the partitions.conf file).

## ipoib

**ipoib**  
**no ipoib**

Enables this partition to use IPoIB. As a result IPoIB multicast group will be created. The no form of the command will remove the use of IPoIB in this partition (it will not appear in the partitions.conf file).

|                           |                                                                                                                                                |

| <b>Example</b>            | <pre>switch (config) # ib partition my-partition switch (config partition my-partition) # ipoib switch (config partition my-partition) #</pre> |
| <b>Related Commands</b>   | rate<br>mtu<br>sl<br>scope                                                                                                                     |
| <b>Note</b>               | “rate”, “mtu”, “sl” and “scope” commands can be used only when the IPoIB parameter is enabled.                                                 |

## mtu

**mtu** <256, 512, 1K, 2K,4K>

**no mtu**

Specifies MTU for this IPoIB multicast group.  
The no form of the command sets the mtu to default (it will not appear in the partitions.conf file).

| Syntax Description        |                                                                                                                                                 |

| <b>Example</b>            | <pre>switch (config) # ib partition my-partition switch (config partition my-partition) # mtu 4K switch (config partition my-partition) #</pre> |
| <b>Related Commands</b>   | ipoib                                                                                                                                           |
| <b>Note</b>               | IPoIB parameter on the partitions must be enabled in order to use this parameter                                                                |

## rate

**rate <rate>**

**no rate**

Specifies rate for this IPoIB multicast group.  
The no form of the command set the rate to default (removes the rate from the partitions.conf)

|                           |                                                                                                                                                  |                                                                                                                                                                                                                                                                                                 |

## scope

**scope** <type>

**no scope** <link-local, site-local, organization-local, global>

Specifies scope for this IPoIB multicast group.  
The no form of the command removes the scope configuration from the partitions.conf file

| <b>Note</b>               | ipoib parameter on the partitions must be enabled in order to use this parameter.                                                                     |                                                          |

## sl

**sl** <0-14, "default">

**no sl**

Specifies SL (Service Level - QoS) for this IPoIB multicast group.  
The no form of the command sets it to default (the sl configuration is removed from the partitions.conf file).

### 7.4.4.3 Quality of Service (SM)

## ib baseqos <port-type> high-limit

**ib baseqos <port-type> high-limit <count>**

Sets the high-limit value for the indicated port type. Thus the system will send at least  $4096 * \text{<count>}$  bytes from the high priority list before sending any from the low priority list.

|                           |                                                                                                        |                                                                                                                                                                                                                 |

## ib baseqos <port-type> sl2vl

**ib baseqos <port-type> sl2vl {sl0 | sl0 sl1 | sl0 sl1 sl2 |...}**

**no ib baseqos <port-type> sl2vl**

Sets a list of up to 16 entries that map the SL entry to an appropriate VL.  
The no form of the command sets the attributes to their default settings.

## ib baseqos <port-type> vlarb-high <value>

**ib baseqos <port-type> vlarb-high {VW1 | VW1 VW2 | ...}**

**no ib baseqos <port-type> vlarb-high**

Sets up to 15 VL to Weight mapping pairs for high priority processing.  
The no form of the command sets the attributes to their default settings.

## ib baseqos <port-type> vlarb-low <value>

**ib baseqos <port-type> vlarb-low {VW1 | VW1 VW2 | ...}**

**no ib baseqos <port-type> vlarb-low**

Sets up to 15 VL to Weight mapping pairs for low priority processing.  
The no form of the command sets the attributes to their default settings.

## ib qos

**ib qos**  
**no ib qos**

Enables advanced QoS management on this node  
 The no form of the command disables advance QoS on this node.

## ib qos level

**ib qos level** {<name> | default} {mtu-limit <mtu> | packet-life <time> | pkey <number> | rate-limit <rate-value> | sl <sl-value> | use <description>}  
**no ib qos level** {<name> | default} {mtu-limit | packet-life | pkey | rate-limit | sl | use}

Specifies a QoS level <name> or “default” parameters.  
 The no form of the command set the parameters to default.

| <b>Role</b>               | admin                                                                                                                                            |                                                                                                                                                                                                              |

---

**Example**

```
switch (config) # ib qos level my-qos-group mtu-limit 2K
switch (config) # show ib qos my-qos-group
my-qos-group:
 use = default QoS Level
 sl = 0
 mtu-limit = 2K
 rate-limit = default
 packet-life = 0x12
 pkey = -1
switch (config) #
```

## ib qos match-rule

**ib qos match-rule** <rule-index> { {destination | source} <string> | {pkey | qos-class | service-id} <index> {first | last} <value>} | qos-level-name <name>| use <description>}

**no ib qos match-rule** <rule-index> { {destination | source} | {pkey | qos-class | service-id} <index> {first | last} } | qos-level-name | use }

Manages QoS Policy match rules.

The no form of the command set the QoS match-rule to default.

## ib qos port-group

**ib qos port-group** <name> {node-type <index> type <node-type> | partition <name> | pkey <number> | port-guid <index> {first | last} <value> | port-name <index> name <name-value> | use <description>}

**no ib qos port-group** <name> {node-type <index> type | partition | pkey | port-guid <index> {first | last} | port-name <index> name | use }

Manages QoS Policy port groups.

The no form of the command removes a QoS port-group.

## 7.5 Subnet Manager (SM) High Availability (HA)

All nodes in an SM HA subnet must be of the same CPU type (i.e. PPC or x86).

High availability (HA) refers to a system or component that is continuously operational for a desirably extended period of time. The following sections introduce two types of high availability.

**Figure 36: SM HA Subnet**

All the systems in an InfiniBand subnet must be connected to the same Ethernet subnet to enable data synchronization through the mgmt0 interface.

Mellanox Subnet Manager (SM) HA reduces subnet downtime and disruption as it is continuously operational for a desirably long length of time. It assures continuity of the work even when one of the SMs dies. The database is synchronised with all the nodes participating in the InfiniBand subnet and a configuration change is prepared. The synchronization is done out-of-band using an Ethernet management network.

Mellanox SM HA allows the systems' manager to enter and modify all InfiniBand SM configuration of different subnet managers from a single location. It creates an InfiniBand subnet and associates all the Mellanox management appliances that are attached to the same InfiniBand subnet into that InfiniBand subnet ID. All subnet managers can be controlled, started, or stopped from this address.

All the nodes that participate in the Mellanox SM HA are joined to the InfiniBand subnet ID and once joined, the synchronized SMs are launched. One of the nodes is elected as Master and the others are Slaves (or down). Mellanox SM HA uses an IP address (VIP) that is always directed to the SM HA master to monitor the SM state and to verify that all configurations are executed.

### 7.5.1 Joining, Creating or Leaving an InfiniBand Subnet ID

When transitioning from standalone into a group or vice versa, a few seconds are required for the node state to stabilize. During that time, group features such as Gateway HA, SM HA, and MLAG commands should not be executed. To run group features, wait for the CLI prompt to turn into [standalone:master], [<group>:master] or [<group>:standby] instead of [standalone:\*unknown\*] or [<group>:\*unknown\*].

An InfiniBand subnet is formed by a network of InfiniBand nodes interconnected via InfiniBand switches. It includes all systems that can run an SM and is part of the SM HA domain. A switch

that can potentially run an SM must be a member of an InfiniBand subnet ID to be associated with the Mellanox SM HA domain. An IB subnet is recognized by its ID which is used by the system to either join or leave the subnet.

Every system that is not associated to an existing IB subnet (has never been part of an IB subnet or has left an existing one) or does not have MLNX-OS SwitchX license installed, is by default associated to a subnet called “Standalone”.

In order to create, join or leave an InfiniBand subnet, one may use the following commands:

- Create – “ib ha <IB\_subnet\_ID> ip <ip\_addr> <netmask>”
- Join – “ib ha <IB\_subnet\_ID>”
- Leave – “no ib ha”

For further information see [Section 7.5.5, “Creating and Adding Systems to an InfiniBand Subnet ID,” on page 1155](#).

### 7.5.2 MLNX-OS Management Centralized Location

MLNX-OS centralized management infrastructure enables the user to configure or modify an existing configuration and monitor the subnet running status. MLNX-OS centralized management IP (VIP) is defined when a new subnet manager is created by running the command `ib ha <IB_subnet_ID> ip <ip_addr> <netmask>`. The created VIP is used as the current subnet master’s alias thus, assumes the same roles as the master.

The VIP always points to one of the systems part of the SM HA domain. It is always active even if one or more of the members are down. For example:

```
switch [standalone: master] (config) # ib ha subnet2 ip 192.168.10.110
255.255.255.0
switch [subnet2: master] (config) #
```

### 7.5.3 High Availability Node Roles

A node is an InfiniBand switch system. Every node member of an IB subnet ID has one of the following roles:

- Master - the node that manages SM configurations and provides services to the Virtual IP (VIP) addresses
- Standby - the node that replaces the Master node and takes over its responsibilities once the Master node is down
- Offline - has run an SM in the past and is currently Offline, or it was created manually by the “ib smnode <node name> create” command. If the node has been removed from the environment, you can remove it from the list with the “no ib smnode xxx” command.

➤ **To see the mode of the current node, look at the CLI prompt for the following format:**

```
<host name> [<subnet ID>:<mode>] [standalone: master] (config) #
```

For example:

```
switch [ibstandalone: master] (config) #
```

To see a list of the existing nodes and details about the running state, run the command `show ib smnodes {brief}`.

## 7.5.4 Configuring MLNX-OS SM HA Centralized Location

The IP is used to configure or modify the existing configuration and monitor the subnet running status.

### ➤ *To configure the IP:*

**Step 1.** Enter config mode. Run:

```
switch [standalone: master] >
switch [standalone: master] > enable
switch [standalone: master] # configure terminal
```

**Step 2.** Configure your IP using the `ib ha <IB_subnet_ID> ip <ip_addr> <netmask>` command.

```
switch [standalone: master] (config) # ib ha subnet2 ip 192.168.10.110 255.255.255.0
switch [subnet2: master] (config) #
```

## 7.5.5 Creating and Adding Systems to an InfiniBand Subnet ID

### ➤ *To create and add systems to a subnet:*

**Step 1.** Log into the system from where you are creating the subnet.

**Step 2.** Enter config mode. Run:

```
switch [standalone: master] >
switch [standalone: master] > enable
switch [standalone: master] # configure terminal
```

**Step 3.** Create a new subnet using the `ib ha <IB_subnet_ID> ip <ip_addr> <netmask>` command.

```
switch [standalone: master] (config) # ib ha subnet2 ip 192.168.10.110 255.255.255.0
switch [subnet2: master] (config) #
```

You must run the `ib ha <IB_subnet_ID> ip <ip_addr> <netmask>` command **only once** per subnet ID.

**Step 4.** Log into the system that you are going to join to the new created subnet.

**Step 5.** Join the system to the subnet, using the `ib ha <IB_subnet_ID>` command.

```
switch [standalone: master] (config) # ib ha subnet2
switch [subnet2: standby] (config) #
```

## 7.5.6 Restoring Subnet Manager Configuration

In cases where the Subnet Manager configuration becomes corrupted or the subnet manager cannot raise any logical links it is suggested that you restore the default SM configuration.

### ➤ *To restore subnet manager configuration:*

**Step 1.** Enter config mode. Run:

```
switch [subnet2: master] > enable
switch [subnet2: master] # configure terminal
switch [subnet2: master] (config) #
```

**Step 2.** Run the command `ib sm reset-config`.

```
switch [subnet2: master] (config) # ib sm reset-config
```

Example:

```
switch-11a15e [SX: master] (config) # show ib smnodes brief
```

```
HA state of the switch
```

```
=====
```

```
IB Subnet HA name: SX
```

```
HA IP address: 172.30.0.12/24
```

```
Active HA nodes: 2
```

```
IDSM-HA state IPSMPriority
```

```

```

```
*switch-11a15emaster 172.30.0.10enabled - master0
```

```
switch-1133f6standby 172.30.0.11enabled2
```

```
switch-11a15e [SX: master] (config) # show ib smnodes
```

```
HA state of the switch
```

```
=====
```

```
IB Subnet HA name: SX
```

```
HA IP address: 172.30.0.12/24
```

```
Active HA nodes: 2
```

```
HA node local information
```

```
Name: switch-11a15e (active) <--- (local node)
```

```
SM-HA state: master
```

```
SM Licensed: yes
```

```
SM Running: running
```

```
SM Enabled: enabled - master
```

```
SM Priority: 0
```

```
IP: 172.30.0.10
```

```
HA node local information
```

```
Name: switch-1133f6 (active)
```

```
SM-HA state: standby
```

```
SM Licensed: yes
```

```
SM Running: stopped
```

```
SM Enabled: enabled
```

```
SM Priority: 2
```

```
IP: 172.30.0.11
```

```
switch-11a15e [SX: master] (config) #
```

The asterisk in the example above (**\*switch-11a15e**) indicates the local system from where the command is running.

In order to receive information on the running state of a specific node one could run one of the following commands with its requested parameter:

- `show ib smnode <name> sm-licensed`
- `show ib smnode <name> sm-running`
- `show ib smnode <name> sm-state`
- `show ib smnode <name> sm-priority`
- `show ib smnode <name> active`
- `show ib smnode <name> ha-state`
- `show ib smnode <name> ha-role`

### 7.5.6.1 Subnet Manager Configuration

To configure the subnet manager, log into the centralized management IP (VIP). Once the SM configuration is created, the SM database is duplicated to the other nodes.

The SM **must** be configured from MLNX-OS centralized management IP (VIP). All the configurations that are not created or modified in the master node (using the VIP) are overridden by the master configuration.

The user can configure different SM parameters such as where to run the SM(s) or the SM priority by running the commands according to the desired action.

### 7.5.6.2 Mellanox High Availability and Opensm Handover/Failover

Mellanox Technologies products are fully compliant and interoperable with OpenSM.

Once an SM fails, the SM which takes over the subnet needs to reproduce the internal state of the failed master. Most of the information required is obtained by scanning the subnet and extracting the information from the devices. However, some information which is not stored directly in the network devices cannot be reproduced this way. InfiniBand management architecture limits such information to data exchanged between clients (either user-level programs or kernel modules) and the Subnet Administration (SA) service (attached to the SM). The SA keeps this set of client registrations in an internal data structure called SA-DB. The SA-DB information includes the multicast groups, the multicast group members, subscriptions for event forwarding and service records.

The new SM may retrieve the SA-DB by requesting the clients to re-register with the SA or by obtaining a copy of the previous master SM internal SA-DB via an SA-DB dump file. The client-re-registration offers database correctness and the SA-DB dump file replication provides lower setup time. Client re-registration is required since the SA-DB may not be up-to-date on the registrations listed in the master SM.

Furthermore, since the SM does not maintain SA-DB information for unknown nodes, it is very possible that some of the SA-DB information relating to nodes momentarily disconnected from the master SM become purged. Therefore, these nodes must re-register with the new SM when they are reconnected (they receive a client-re-register request from the SM). Relying only on client re-registration is also non-optimal as it takes some time to recreate the entire SA-DB and the network state.

Mellanox SM HA replicates the SA-DB dump file from the current master SM to all the standby SMs running on Mellanox switches. The SA-DB dump file replication provides further optimization to the standby SM that becomes master.

Standby SM loads the existing SA-DB file the old master has used. By using the existing SA-DB the amount of processing needed on client re-registration is lessened resulting in a reduced time to complete setting up the network.

SM HA does not replace InfiniBand spec requirement for client reregistration.

## 7.5.7 Commands

### ib ha

**ib ha <IB\_subnet\_ID> [ip <IP address> <subnet mask> [force]]**  
**no ib ha**

Creates a subnet <IB\_subnet\_ID> with the specified IP.  
 The no form of the command removes this node from an InfiniBand subnet ID.

| <b>Default</b>            | N/A                                                                                                                                                                                                                                                                                   |                                         |
| <b>Configuration Mode</b> | Config                                                                                                                                                                                                                                                                                |                                         |
| <b>History</b>            | 3.1.0000                                                                                                                                                                                                                                                                              |                                         |
| <b>Role</b>               | admin                                                                                                                                                                                                                                                                                 |                                         |
| <b>Example</b>            | switch (config) # ib ha my-subnet<br>switch (config) #                                                                                                                                                                                                                                |                                         |
| <b>Related Commands</b>   | show ib ha                                                                                                                                                                                                                                                                            |                                         |
| <b>Note</b>               | <ul style="list-style-type: none"> <li>• A new subnet may be joined only after leaving the current one</li> <li>• All SM HA cluster members should be part of the same switch family (e.g. all members are part of SX60XX family or all members are part of SX65XX family)</li> </ul> |                                         |

## ib smnode

**ib smnode <hostname> [create | disable | enable | sm-priority <priority>]**  
**no ib smnode <hostname> [create | disable | enable | sm-priority]**

Manages HA SM.

The no form of the command removes HA SM node configuration.

|                           |                                                                               |                                                  |

switch [subnet2: master] (config) #

```

## 7.6.2 Mapping GUIDs to Node Names

To replace module GUIDs and assign meaningful names to modules use the `ib nodename` command. For further information, see *MLNX-OS CLI User Guide*.

## 7.6.3 Importing ibdiagnet Fabric Data

The `ib fabric import <fabric data filename>` command imports a “snapshot” of fabric data. The imported file is an output of the `ibdiagnet` tool that has previously run on any node connected to the fabric. Prior to importing fabric data, it is required to run the `ibdiagnet` tool to produce fabric data files.

Note that there are two versions of the `ibdiagnet` tool. The earlier version produces three output files describing the fabric (`ibdiagnet.db`, `ibdiagnet.pm`, and `ibdiagnet.sm`), whereas the new version produces a single file (`ibdiagnet.db_csv`).

### ➤ To make an *ibdiagnet* run and import its fabric data:

#### Step 1. Collect *ibdiagnet* data.

Run the following command from any node connected to the fabric. By default, `ibdiagnet` places the output file(s) under `/tmp`.

*Old ibdiagnet version:*

```
> ibdiagnet -csv -skip dup_guids zero_guids logical_state part ipoib -pm
```

*New ibdiagnet version:*

```
> ibdiagnet -pm
```

**Step 2.** Change directory to the ibdiagnet output directory.

The default directory is /tmp.

```
> cd <ibdiagnet output directory>
```

**Step 3.** Create an ibdiagnet output tarball. Run:

```
> tar cvzf <filename>.tgz ibdiagnet*
```

**Step 4.** Copy the tarball <filename>.tgz to the switch using the `image fetch` command. Run (in enable or config mode):

```
switch # image fetch scp://<user name>:<password>@<hostname>/<full path to <file-
name>.tgz>
100.0%[#####]
#####]
switch #
```

**Step 5.** Import the ibdiagnet file(s). Run:

```
switch [subnet2: master] (config) # ib fabric <filename>.tgz
Fabric data import successful
switch [subnet2: master] (config) #
```

## 7.6.4 Commands

### ib fabric import

**ib fabric import <filename>**

Imports a “snapshot” of fabric data. It retrieves fabric data from the following ibdiagnet output files: ibdiagnet.db, ibdiagnet.sm and ibdiagnet.pm.

## ib fabric refresh

### ib fabric refresh

Takes a “snapshot” of the current fabric data.

|                           |                                                                                                                                |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax Description</b> | N/A                                                                                                                            |
| <b>Default</b>            | N/A                                                                                                                            |
| <b>Configuration Mode</b> | Config                                                                                                                         |
| <b>History</b>            | 3.1.1400                                                                                                                       |
| <b>Role</b>               | admin                                                                                                                          |
| <b>Example</b>            | switch (config) # ib fabric refresh<br>switch (config) #                                                                       |
| <b>Related Commands</b>   | show ib fabric nodes                                                                                                           |
| <b>Note</b>               | If the fabric is large, this command may take a long time to complete.<br>this command requires license (LIC-fabric-inspector) |

## ib fabric transceiver-info

**ib fabric transceiver-info enable**  
**no ib fabric transceiver-info enable**

Enables collection of active cable info.  
 The no form of the command disables collection of active cable info.

| <b>Role</b>               | monitor/admin |

**Example**

```

switch (config) # (config) # test ib fabric
% -----
-I- Plugins load will be skipped

Discovery
-I- Discovering ... 1 nodes (1 Switches & 0 CA-s) discovered.
-I- Discovery finished successfully

-I- Duplicated GUIDs detection finished successfully

-I- Duplicated Nodes Descriptions detection finished successfully

Lids Check
-E- Lids Check finished with errors
-E- IBM-QA-Bay3: SX90Y3245/U1/P0 - Configured with ZERO lid

Links Check
-I- Links Check finished successfully

Subnet Manager
-I- SM Info retrieving finished successfully

-E- Subnet Manager Check finished with errors
-E- Not found master subnet manager in fabric

Port Counters
-I- Lids Check failed, no response for some MADs can occurred
-I- Ports counters retrieving finished successfully

-I- Ports counters value Check finished successfully

-I- Ports counters Difference Check will be skipped - pause time is zero

Nodes Information
-I- Lids Check failed, no response for some MADs can occurred
-W- Nodes Info retrieving finished with errors
-W- IBM-QA-Bay3: SX90Y3245/U1 - No response for MAD VSGeneralInfo

-I- FW Check finished successfully

Speed / Width checks
-I- Link Speed Check (Compare to supported link speed)
-I- Links Speed Check finished successfully

-I- Link Width Check (Compare to supported link width)
-I- Links Width Check finished successfully

Summary
-I- Stage Warnings Errors Comment
-I- Discovery 0 0
-I- Lids Check 0 1
-I- Links Check 0 0
-I- Subnet Manager 0 1
-I- Port Counters 0 0
-I- Nodes Information 1 0
-I- Speed / Width checks 0 0
...
switch (config) #

```

**Related Commands**

**Note**

## show ib fabric connections

**show ib fabric connections [attrib <speed/width>] [details] [type]**

Displays the ib fabric connections with optional relevant filter.

| <b>Note</b>               | If enabled, transceiver info will be gathered by the InfiniBand fabric.                 |

## 8 Gateway

Gateway is not supported in MLNX-OS release 3.4.1110.

When the network consists of two types of link protocols (Ethernet and InfiniBand), Proxy-ARP can be used to forward IPv4 packets from the Ethernet network to the InfiniBand network and vice versa. Proxy-ARP is not an IP Router, but acts as a bridge that forwards the IPoETH packets to IPoIB in Unreliable Datagram (UD).

The Proxy-ARP forwards the traffic in a single subnet.

IP Routing, InfiniBand SM and IGMP snooping must be disabled to enable Proxy-ARP.

### 8.1 Proxy-ARP Prerequisites

Before trying to configure a Proxy-ARP in the system make sure the following conditions are met:

- Gateway license is installed (UPGR-XXXX-GW) on the switch. Run the command `show system capabilities` to verify that.

The switch system SX6036G does not require a Gateway license.

- The system profile is `vpi-single-switch`. Run the command `show system profile` to verify that. For additional information on the system profile refer to [Section 4.5, “System Profile,”](#) on page 176.
- InfiniBand and Ethernet interfaces are mapped on the system. Run the command `show ports type` to verify that. For additional information on the port mapping refer to [Section 4.4, “Virtual Protocol Interconnect \(VPI\),”](#) on page 172.
- IP routing is disabled. To disable it run:

```
switch (config)# no ip routing
```

- IGMP snooping is disabled. To disable it run:

```
switch (config)# no ip igmp snooping
```

- InfiniBand SM is disabled. To disable it run:

```
switch (config)# no ib sm
```

## 8.2 Proxy-ARP Overview

**Figure 38: Basic Gateway Setup**

### 8.2.1 Proxy-ARP Modes

Proxy-ARP supports unicast and multicast modes.

Multicast configuration is not available in unicast mode.

Proxy-ARP modes can be configured only when Proxy-ARP is disabled (no ip proxy-arp).

When Proxy-ARP modes are modified, interface configuration is removed. The user is prompted to approve this.

#### 8.2.1.1 Proxy-ARP Unicast

An ARP request sent from an InfiniBand host is terminated at the Proxy-ARP. Then a new ARP request is generated and sent on the VLAN interface to reach the Ethernet host. The Ethernet host responds with an ARP reply to the Proxy-ARP. The Proxy-ARP then terminates it and generates a new ARP reply to the InfiniBand host. Once the destination address has been resolved, unicast traffic is passed from the InfiniBand host to the Ethernet host. The process is similar in the opposite direction (Ethernet to InfiniBand).

**Figure 39: Unicast ARP Flow**

Table 54 details traffic forwarding in unicast (UC) mode.

**Table 54 - IPoIB Forwarding**

| Case                                                                                                 | IPoETH-to-IPoIB                                                | IPoIB-to-IPoETH                                        |
|------------------------------------------------------------------------------------------------------|----------------------------------------------------------------|--------------------------------------------------------|
| Unicast                                                                                              | Forward according to HA load balancing algorithm. <sup>1</sup> | Forward according to HA load balancing algorithm.      |
| Multicast                                                                                            | Drop                                                           | Drop                                                   |
| Broadcast (255.255.255.255); Subnet broadcast                                                        | Forward by software in case the box is the GLBP master         | Forward by software in case the box is the GLBP master |
| Master advertisement MC group (239.0.0.77); all-node group (224.0.0.1); all-router group (224.0.0.2) | Does not forward (local termination)                           | Does not forward (local termination)                   |

1. See Section 8.2.2.4, “Proxy-ARP Load Balancing,” on page 1196

### 8.2.1.2 Proxy-ARP Multicast

Broadcast and subnet broadcast are supported in Proxy-ARP HA and are forwarded by the GLBP master.

With IB-to-ETH multicast (MC) flow, the Proxy-ARP signs up to receive InfiniBand MC notifications. Upon InfiniBand MC group creation, the Proxy-ARP is notified and as a result, the Proxy-ARP sends a join request and triggers IGMP query. The host then receives the query and sends an IGMP join request which is forwarded to the MC router on the Ethernet side.

With ETH-to-IB MC flow, MC traffic is forwarded to the Proxy-ARP. The Proxy-ARP forwards the packet to the InfiniBand side only if a MC group is created (a MC route configured on the Proxy-ARP or dynamically according to the flow above). Otherwise, it would be dropped.

We assume that the MC router is on the Ethernet side.

Table 55 specifies how Proxy-ARP forwards multicast traffic.

**Table 55 - IPoIB Multicast Forwarding**

| Case                                                                        | IPoETH-to-IPoIB                                        | IPoIB-to-IPoETH                                        |
|-----------------------------------------------------------------------------|--------------------------------------------------------|--------------------------------------------------------|
| Unicast                                                                     | Forward                                                | Forward                                                |
| Multicast                                                                   | Forward according to HA load balancing algorithm       | Forward according to HA load balancing algorithm       |
| Broadcast (255.255.255.255); Subnet broadcast; All-router group (224.0.0.2) | Forward by software in case the box is the GLBP master | Forward by software in case the box is the GLBP master |
| All-node group (224.0.0.1)                                                  | Forward in case the box is the GLBP master             | Forward in case the box is the GLBP master             |

## 8.2.2 Proxy-ARP High Availability

All nodes in a Proxy-ARP HA group must feature of the same CPU type (i.e. PPC or x86).

Proxy-ARP interfaces support IGMPv2 only.

High availability (HA) refers to a system or component that is continuously operational for a desirably extended period of time. The following sections introduce Mellanox high availability Proxy-ARP.

**Figure 41: High Availability Proxy-ARP Interface**

All gateway nodes must be on the same management IP subnet.

Proxy-ARP HA reduces downtime and disruption as it is continuously operational for a desirably long length of time. It assures continuity of the work even when one Gateway fails. The database is synchronized with all the nodes participating in the Proxy-ARP group and a configuration change is prepared. The synchronization is done out-of-band using an Ethernet management network.

All the nodes that participate in the Proxy-ARP group are joined under a Proxy-ARP group name. One of the nodes is elected as master and the others become slaves. Proxy-ARP HA uses an IP address (VIP) that is always directed to the master node. The configuration is set via the VIP to the master node which in turn distributes it to the slave nodes.

The VIP address should be on the same management IP subnet.

### 8.2.2.1 Joining, Creating or Leaving a Proxy-ARP HA Group

When transitioning from standalone into a group or vice versa, a few seconds are required for the node state to stabilize. During that time, group features such as Gateway HA, SM HA, and MLAG commands should not be executed. To run group features, wait for the CLI prompt to turn into [standalone:master], [<group>:master] or [<group>:standby] instead of [standalone:\*unknown\*] or [<group>:\*unknown\*].

A Proxy-ARP group is formed by a network of Gateway nodes. Each group may be composed of up to 16 nodes. A Proxy-ARP group has a name identifier used for joining or leaving the group.

To create, join or leave a Gateway subnet, one may use the following commands:

- Create – proxy-arp ha <group-name> ip <ip\_addr> <mask>
- Join – proxy-arp ha <group-name>
- Leave – no proxy-arp ha

For further information see [Section 8.2.2.6, “Managing High-Availability Proxy-ARP Groups,” on page 1197](#).

### 8.2.2.2 MLNX-OS Management Centralized Location

MLNX-OS centralized management infrastructure enables the user to configure or modify an existing configuration and monitor a Proxy-ARP group’s running status. MLNX-OS centralized management IP (VIP) is defined when the first Proxy-ARP HA group member is added by using the command proxy-arp ha <group-name> ip <ip\_addr> <mask>. Proxy-ARP HA always directs the configured IP address (VIP) to the master node.

The VIP is always serviced by the node which is currently the master of the HA group. It is always active even if one or more of the members are down.

### 8.2.2.3 High Availability Node Roles

A node, in this case, is a Gateway switch system. Every node member of a Proxy-ARP HA group has one of the following roles:

- Master – the node that manages HA configurations and service to the VIP addresses.
- Standby – each node that can replace the master node and take over its responsibilities once the master node is down

Nodes support the following functions:

- Discovery – network discovery
- Master election – electing a master node among the nodes running in a group.
- Failure detection – detecting failure if a node goes down. In case of failure the system recovers and ensures a master node is available.
- Configuration replication – configuration on the master node is replicated on the slave node.

➤ **To see the mode of the current node, look at the CLI prompt for the following format:**

```
<host name> [<subnet ID>:<mode>] (config) #
```

To see a list of the existing nodes and details about the running state, run the command show proxy-arp ha.

### 8.2.2.4 Proxy-ARP Load Balancing

Changing box mode from single box to HA for the first time may cause traffic loss for up to 1 minute.

Changing modes from HA to single-box removes member related configuration.

Proxy-ARP HA features two load balancing modes:

- Active-Active – the Gateway nodes within the group are all active and share the traffic load
- Active-Standby – one Gateway nodes handles all the traffic while the others are on standby mode

The Active-Active load balancing algorithm is based on a VRRP-like protocol. IP addresses of hosts are distributed between the active Gateway systems. Upon adding or removing a new member the load is redistributed among the members accordingly. To minimize traffic loss, when a member is added, traffic is passed to it only once the new member is operationally ready. Once the new member begins serving a group of IP hosts, it sends gratuitous ARPs for the purpose of rapid stabilization. Other than in cases when a Proxy-ARP HA member leaves or joins the group, traffic does not move between existing members so as to minimize loss of traffic.

Active-Active load balancing is of three types:

- InfiniBand base IP – based on the destination IP for Ethernet sourced traffic, and source IP for InfiniBand sourced traffic
- Ethernet base IP – based on the destination IP for InfiniBand sourced traffic, and source IP for Ethernet sourced traffic
- Source IP Destination IP – best distribution of traffic when many hosts are populated on both sides

In Active-Standby load balancing the Proxy-ARP HA member with the highest priority is the one selected to pass the traffic. However, if two members have the same priority, the one with the highest GUID number carries all the traffic.

Member nodes in the Proxy-ARP HA group are organized into a virtual ring. Within this group, the following fail scenarios may occur depending on the failing node:

- Master fails – the standby detects it, becomes master, and selects a new standby node from the list of members making failover fast
- Standby fails – the master selects a new standby out of the remaining members

### 8.2.2.5 Prerequisites

The HA Proxy-ARP prerequisites match those of the standalone Proxy-ARP prerequisites. Refer to [Section 8.1, “Proxy-ARP Prerequisites,”](#) on page 1190.

### 8.2.2.6 Managing High-Availability Proxy-ARP Groups

➤ *To create and add systems to a subnet:*

**Step 1.** Log into the system from where you are creating the subnet.

**Step 2.** Create a new Proxy-ARP group using the command `proxy-arp ha <group-name> ip <ip_addr> <mask>`. Run:

```
GatewayA [standalone: master] (config) # proxy-arp ha my-group ip 10.10.10.10 /24
GatewayA [my-group: master] (config) #
```

You must run the command `proxy-arp ha <group-name> ip <ip_addr> <mask>` **only once** per Proxy-ARP group.

The group IP is used to as a single point for gateway configuration and monitoring the subnet's running status (by running "show" commands).

**Step 3.** Log into the system that you are going to join to the new created Proxy-ARP group.

**Step 4.** Join another system to the Proxy-ARP group, using the command `proxy-arp ha <group-name>`. Run:

```
GatewayB [standalone: master] (config) # proxy-arp ha my-group
GatewayB[my-group: standby] (config) #
```

Once a Proxy-ARP HA group is created, the first member maintains its configuration. Configuration of the Proxy-ARP HA may then be performed to suit the subnet needs. When new nodes join the group, the configuration is duplicated to them.

A new node joining a group should serve all the interfaces. For each interface addition, set the Member IP addresses using the command `interface proxy-arp <pra-id> ha member <hostname> ip address <ip-address>`.

Removing a member from an active Proxy-ARP group must be done using the command `no proxy-arp ha` from the box management interface.

### 8.2.3 Proxy-ARP Interface

Proxy-ARP is a logical interface which owns the IP address, VLAN and PKEY values of the subnet.

**Figure 42: Proxy-ARP Interface**

The Proxy-ARP interface has the following attributes:

**Table 56 - Proxy-ARP Interface Attributes**

| Parameter         | Description                                               | Scope            | Access |
|-------------------|-----------------------------------------------------------|------------------|--------|
| Admin state       | Enables or disables the interface                         | Interface        | RW     |
| Operational state | Shows the operational state of the interface (up or down) | Interface member | RO     |
| Description       | Sets an alias text to the interface                       | Interface        | RW     |
| IP address        | IP address                                                | Interface member | RW     |
| IP netmask        | Network prefix mask                                       | Interface        | RW     |
| GUID              | Interface GUID                                            | Interface member | RO     |
| MTU               | Maximum transmission unit                                 | Interface        | RW     |
| VLAN              | VLAN value                                                | Interface        | RW     |
| PKEY              | PKEY value                                                | Interface        | RW     |
| Counters admin    | Enables a set of counters on the interface                | Interface        | RW     |
| Set of counters   | Interface counters                                        | Interface member | RO     |
| Priority          | Interface member priority                                 | Interface member | RW     |
| HA timers         | Timers the control Proxy-ARP HA behavior                  | Interface member | RW     |
| Multicast routes  | Multicast                                                 | Interface        | RW     |

## 8.2.4 Proxy-ARP Resources

### 8.2.4.1 Proxy-ARP Unicast Resources

The resources available for UC Proxy-ARP as a standalone box or HA with Active-Standby load balancing are as follows:

- Number of UC routes – 160
- Number of Ethernet ARP entries – 512
- Number of InfiniBand ARP entries – 3520

The resources available for UC Proxy-ARP as HA IB based IP mode with Active-Active load balancing are as follows:

- Number of UC routes – 160
- Number of Ethernet ARP entries – 512
- Number of InfiniBand ARP entries – 3520 times the number of nodes in the Gateway HA Group

### 8.2.4.2 Proxy-ARP Multicast Resources

The resources available for MC Proxy-ARP as standalone box or HA Active-Standby load balancing are as follows:

- Number of UC routes – 160
- Number of Ethernet ARP entries – 128
- Number of InfiniBand ARP entries – 1024
- Number of MC routes – 2500

The resources available for MC Proxy-ARP as HA IB based IP mode with Active-Active load balancing are as follows:

- Number of UC routes – 160
- Number of Ethernet ARP entries – 128
- Number of InfiniBand ARP entries – 1024 times number of nodes in Gateway HA group
- Number of MC routes – max (2500 times the number of nodes in Gateway HA group = 3072)

Due to a resource limitation in the number of sockets that can be opened, the number of static MC groups that can be configured while in a cluster has been limited to 600. In other words, if more than 600 static MC groups are configured on the switch, and the user attempts to join a cluster, the operation fails.

## 8.3 Proxy-ARP Configuration

### 8.3.1 Proxy-ARP Mode Configuration

➤ *To transition from unicast to multicast:*

```
switch [standalone: master] (config) # proxy-arp mode multicast

Warning! All proxy-arp interfaces configuration is going to be deleted.
Type 'yes' to confirm mode change: yes

switch [standalone: master] (config) # show proxy-arp mode
Proxy-arp mode: multicast
Resource Total

ETH hosts 128
IB hosts 1024
Unicast routes 160
Multicast routes 2500
```

➤ *To transition from multicast to unicast:*

```
switch [standalone: master] (config) # proxy-arp mode unicast

Warning! All proxy-arp interfaces configuration is going to be deleted.
Type 'yes' to confirm mode change: yes

switch [standalone: master] (config) # show proxy-arp mode
Proxy-arp mode: unicast
Resource Total

ETH hosts 512
IB hosts 3520
Unicast routes 160
Multicast routes 0
```

### 8.3.2 Standalone Proxy-ARP Configuration

➤ *To configure Proxy-ARP in the system:*

**Step 1.** Make sure the prerequisites conditions are met. Verify that gateway is supported as part of the system capabilities. Run:

```
switch [standalone: master] (config)# show system capabilities
IB: Supported
Ethernet: L3
GW: Supported
Max SM nodes:648
Ethernet Max licensed speed: 40Gbps
IB max licensed speed: FDR
switch [standalone: master] (config)#
```

**Step 2.** Set Proxy-ARP mode. Run:

```
switch [standalone: master] (config)# proxy-arp mode multicast
```

Proxy-ARP mode is unicast by default. This step should only be performed if you wish to configure multicast routes.

**Step 3.** Enable Proxy-ARP. Run:

```
switch [standalone: master] (config)# ip proxy-arp
```

**Step 4.** Create a Proxy-ARP interface. Run:

```
switch [standalone: master] (config)# interface proxy-arp 1
switch [standalone: master] (config interface proxy-arp 1)#
```

**Step 5.** Set an IP address and network mask to the Proxy-ARP interface. Run:

```
switch [standalone: master] (config interface proxy-arp 1)# ip address
20.20.20.20
switch [standalone: master] (config interface proxy-arp 1)# ip netmask /24
```

Each Proxy-ARP interface must have a unique IP subnet.

The Proxy-ARP interface IP must be on a different IP subnet than that of the management interfaces.

**Step 6.** Create a VLAN. Run:

```
switch [standalone: master] (config)# vlan 10
switch [standalone: master] (config vlan 10)# exit
```

**Step 7.** Add a VLAN to the interface. Run:

```
switch [standalone: master] (config interface proxy-arp 1)# ip vlan 10
```

**Step 8.** Add a PKEY to the interface. Run:

```
switch [standalone: master] (config interface proxy-arp 1)# ip pkey 0x7fff
```

Each Proxy-ARP interface must have a unique VLAN/PKEY pair.

**Step 9.** Enable the Proxy-ARP interface. Run:

```
switch [standalone: master] (config interface proxy-arp 1)# no shutdown
```

**Step 10.** Make sure one of the Ethernet or port-channel ports are configured with VLAN 10 and that the Proxy-ARP part of the VLAN is operationally up. For example:

```
switch [standalone: master] (config interface ethernet 1/1)# switchport access
vlan 10
switch [standalone: master] (config interface ethernet 1/1)# show interfaces
proxy-arp 1
```

```

Proxy-arp 1
 Admin state: Enabled
 Operational state: Up
 GUID: 00:02:C9:03:00:66:08:63
 Internet Address: 20.20.20.20/24
 Broadcast Address: 20.20.20.255
 Description: N/A
 MTU: 1500
 Counters: Disabled
 Member interfaces: vlan 10, pkey 0x7fff
switch (config)#

```

**Step 11.** (Optional) Configure a route to the default gateway in the subnet. Run:

```

switch [standalone: master] (config interface proxy-arp 1)# ip route default
20.20.20.254

```

The default gateway configuration is not used for management purposes.

**Step 12.** (Optional) Configure a multicast route. While in Proxy-ARP multicast mode, run:

```

switch [standalone: master] (config interface proxy-arp 1)# ip multicast
237.0.1.5

```

➤ **To verify the Proxy-ARP configuration:**

**Step 1.** Display the Proxy-ARP interface configuration. Run:

```

switch [standalone: master] (config)# show interfaces proxy-arp 1
Proxy-arp 1
 Admin state: Enabled
 Operational state: Up
 GUID: 00:02:C9:03:00:66:08:63
 Internet Address: 20.20.20.20/24
 Broadcast Address: 20.20.20.255
 Description: N/A
 MTU: 1500
 Counters: Disabled
 Member interfaces: vlan 10, pkey 0x7fff
switch [standalone: master] (config)#

```

**Step 2.** Display the Proxy-ARP brief status. Run:

```

switch [standalone: master] (config)# show interfaces proxy-arp brief
Interface Description State Member interfaces

Proxy-arp 1 N/A Up vlan 10, pkey 0x7fff
switch [standalone: master] (config)#

```

**Step 3.** Display the routing table. Run:

```
switch [standalone: master] (config) # show ip route interface proxy-arp 1
Destination Mask Gateway Interface Source Distance/Metric
20.20.20.0 255.255.255.0 0.0.0.0 proxy-arp 1 kernel 0/0
default 0.0.0.0 20.20.20.254 proxy-arp 1 static 0/0
switch [standalone: master] (config) #
```

**Step 4.** Display the multicast routing table. Run:

```
switch [standalone: master] (config) # show ip multicast interface proxy-arp 1
Proxy-arp 1 multicast list:

Total number of entries: 5

Address Interface Source

224.0.0.1 proxy-arp 2 Dynamic
224.0.0.2 proxy-arp 2 Dynamic
237.0.1.5 proxy-arp 2 Static
239.0.0.77 proxy-arp 2 Dynamic
255.255.255.255 proxy-arp 2 Dynamic
switch [standalone: master] (config) #
```

### 8.3.3 High Availability Proxy-ARP Configuration

➤ *Configure the following on GatewayA:*

```
ssh admin@10.10.10.11
GatewayA [standalone: master] (config)# vlan 10
GatewayA [standalone: master] (config vlan 10)# exit
GatewayA [standalone: master] (config)# interface ethernet 1/1 switchport
access vlan 10
GatewayA [standalone: master] (config)# proxy-arp mode unicast force
GatewayA [standalone: master] (config)# ip proxy-arp
GatewayA [standalone: master] (config)# proxy-arp ha my-group ip 10.10.10.10
255.255.255.0
GatewayA [my-group: master] (config)
```

➤ *Configure the following on GatewayB:*

```
ssh admin@10.10.10.12
GatewayB [standalone: master](config)# vlan 10
GatewayB [standalone: master] switch (config vlan 10)# exit
GatewayB [standalone: master](config)# interface ethernet 1/1 switchport
access vlan 10
GatewayB [standalone: master](config)# proxy-arp mode unicast force
GatewayB [standalone: master](config)# ip proxy-arp
GatewayB [standalone: master](config)# proxy-arp ha my-group
GatewayB [my-group: standby] (config)
```

The user must make sure all gateway nodes are running with either multicast or unicast mode.

➤ **Configure the following on the VIP:**

```
ssh admin@10.10.10.10
GatewayA [my-group: master] (config)# interface proxy-arp 1
GatewayA [my-group: master] (config interface proxy-arp 1)# ip netmask /24
GatewayA [my-group: master] (config interface proxy-arp 1)# ip vlan 10
GatewayA [my-group: master] (config interface proxy-arp 1)# ip pkey 0x7fff
GatewayA [my-group: master] (config interface proxy-arp 1)# ha member GatewayA
ip address 20.20.20.20
GatewayA [my-group: master] (config interface proxy-arp 1)# ha member GatewayB
ip address 20.20.20.21
GatewayA [my-group: master] (config interface proxy-arp 1)# no shutdown
GatewayA [my-group: master] (config interface proxy-arp 1)# ip route default
10.10.10.250
GatewayA [my-group: master] (config interface proxy-arp 1)# ip multicast
200.0.1.5
```

The IP address of the HA member must not be the IP of the management interface. It should be on a different IP subnet. The HA group IP, however, should be the same IP subnet of the management IP of the system.

➤ **To verify the Proxy-ARP configuration on the VIP:**

```
GatewayA [my-group: master] (config) # show interfaces proxy-arp 1 ha

Proxy-arp 1
 Keep Alive loss threshold: 1
 Keep Alive loss interval: 120 seconds
 Load balancing algorithm: ib-base-ip
 IP masklen: 24
 Admin state: Enabled
 MTU: 1500
 Counters: Disabled
 Bridged interfaces: vlan 10, pkey 0x7fff
 Number of members: 2
 Hostname Description Admin State LB State Operational State IP Priority

 GatewayA host1-dscr Enabled Active Up 20.20.20.20 100
 GatewayB host2-dscr Enabled Active Up 20.20.20.21 100

GatewayA [my-group: master] (config) # show proxy-arp ha
Load balancing: ib-base-ip
Number of Proxy-ARP interfaces: 1

Proxy Arp VIP:
=====
Proxy-arp group name: my-group
HA VIP address: 10.10.10.10/24
Active nodes: 2
Hostname State IP Address

GatewayA master 10.10.10.11
GatewayB standby 10.10.10.12
GatewayA [my-group: master] (config) #
```

➤ **To change the hostname in an active Proxy-ARP HA cluster:**

- Step 1.** Remove Proxy-ARP member configuration related to the switch with the hostname to be renamed.
- Step 2.** Add Proxy-ARP member configuration related to the switch with the new hostname to be configured.
- Step 3.** Wait until load balancing is distributed to all members but this switch.
- Step 4.** Change the switch hostname.
- Step 5.** Save configuration.
- Step 6.** Verify load balancing is distributed to all members.

For example, assuming GatewayA and GatewayB are members of “my-group” and we wish to change GatewayB’s name to GatewayC.

➤ **To create the setup:**

- Step 1.** Connect via interface management of GatewayA. Run:

```
GatewayA [standalone: master] (config) # proxy-arp mode unicast force
GatewayA [standalone: master] (config) # ip proxy-arp
GatewayA [standalone: master] (config) # proxy-arp ha my-group ip 10.10.10.10 /24
GatewayA [my-group: master] (config) #
```

- Step 2.** Connect via interface management of GatewayB. Run:

```
GatewayB [standalone: master] (config) # proxy-arp mode unicast force
GatewayB [standalone: master] (config) # ip proxy-arp
GatewayB [standalone: master] (config) # proxy-arp ha my-group
GatewayB [my-group: standby] (config) #
```

- Step 3.** Connect via VIP. Run:

```
GatewayA [my-group: master] (config)# interface proxy-arp 1 netmast /24
GatewayA [my-group: master] (config)# interface proxy-arp 1 ha member GatewayA ip
20.20.20.20
GatewayA [my-group: master] (config)# interface proxy-arp 1 ha member GatewayB ip
20.20.20.21
GatewayA [my-group: master] (config)# no interface proxy-arp 1 shutdown
```

➤ **To change the hostname from GatewayB to GatewayC:**

- Step 1.** Delete GatewayB member configuration. Connect via VIP. Run:

```
GatewayA [my-group: master] (config) # no interface proxy-arp 1 ha member GatewayB
```

- Step 2.** Configure GatewayC member configuration. Connect via VIP. Run:

```
GatewayA [my-group: master] (config) # interface proxy-arp 1 ha member GatewayC ip
20.20.20.22
```

- Step 3.** Connect through the GatewayB management interface IP, and change the hostname. Run:

```
GatewayB [my-group: standby] (config) # hostname GatewayC
GatewayC [my-group: standby] (config) #
```

## 8.4 Advanced Settings

### 8.4.1 Default Gateway

It is recommended to configure a route to the default gateway in the subnet. If the default gateway is not configured, unregistered unicast traffic is dropped.

### 8.4.2 vTCA Interface

A virtual Target Channel Adapter (vTCA) is an end-point of InfiniBand fabric. Gateway needs a vTCA enabled on the switch in order to function (SMA port #37).

The vTCA is available in VPI single switch mode and when Proxy ARP is enabled.

The vTCA interface is enabled by default. However, if the SM disables this interface, it can be re-enabled by running the following command:

```
switch (config)# no sma port 1 shutdown
switch (config)# show sma port 1
Enabled
switch (config)#
```

When using InfiniBand tools such as iblinkinfo, smpquery, or ibnetdiscover the user is able to see the status of the vTCA interface.

```
iblinkinfo
...
6 37[]==(4X 14.0625 Gbps Active/LinkUp)==> 7 1[] "Mellanox vTCA switch-626a54"
()
...
#

...
...

#
```

### 8.4.3 MTU

Make sure that the InfiniBand subnet MTU is similar to the Ethernet subnet MTU. In most cases the default the MTU is 1500 bytes for Ethernet subnets while 4K in InfiniBand. Run:

```
switch (config)# interface ethernet 1/1 mtu 4000
switch (config)# interface ib 1/10 mtu 4000
switch (config)# interface proxy-arp 1 mtu 4000
```

Proxy-ARP MTU is limited to 4092.

## 8.5 Commands

### 8.5.1 Config

#### ip proxy-arp

**ip proxy-arp**  
**no ip proxy-arp**

Enables Proxy-ARP feature.  
 The no form of the command disables Proxy-ARP feature.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

The no form of the command does not delete Proxy-ARP configuration.</li> <li>This command is not available on VIP.</li> <li>The no form of the command is not available when the box is in an HA group. The user should first leave the group (“no proxy-arp ha &lt;my-group&gt;”) and then use the no form of the command.</li> </ul> |

## proxy-arp mode

**proxy-arp mode {unicast | multicast} [force]**  
**no proxy-arp mode [force]**

Configures IP Proxy-ARP to work in either unicast or multicast mode.  
 The no form of the command resets this parameter to its default.

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• The difference between unicast and multicast mode is in the hardware resource allocation.</li> <li>• The command is only available when IP Proxy-ARP is disabled.</li> <li>• The command is only available from the box IP.</li> <li>• The force parameter in the no form of the command bypasses the confirmation prompt</li> <li>• All Proxy-ARP configurations is deleted upon Proxy-ARP mode change. The user is prompted with a warning message informing him of this, and is required to confirm the command.</li> </ul> |                                    |

## interface proxy-arp

**interface proxy-arp <pra-id>[-<pra-id>]**  
**no interface proxy-arp <pra-id>[-<pra-id>]**

Creates a Proxy-ARP interface, and enters a new configuration mode.  
 The no form of the command deletes the interface configuration.

## proxy-arp ha

**proxy-arp ha <group-name> [ip <ip-address> <ipv-mask> [force]]**  
**no proxy-arp ha**

Creates a Proxy-ARP group or maps the system to an existing group.  
 The no form of the command removes the system from the Proxy-ARP group.

## proxy-arp ha lb-algorithm

**proxy-arp ha lb-algorithm <type>**

**no proxy-arp ha lb-algorithm**

Configures the load balancing algorithm.

The no form of the command resets the value to its default value.

## sma port

**sma port <number> shutdown**  
**no sma port <number> shutdown**

Disables the SMA on virtual TCA.  
 The no form of the command enables the SMA on virtual TCA.

In case the SM disabled this port via MAD interface, this command provides the administrator the ability to re-enable it back (without the need to reload the switch).</li> <li>• SMA ports are currently limited to only one port</li> <li>• In regular operation there is no need to change the configuration of this parameter</li> <li>• This command is applicable via management box IP only.</li> </ul> |                  |

## 8.5.2 Interface Proxy-ARP

### ip address

**ip address <ip-address>**  
**no ip address**

Sets IP address for this interface.  
 The no form of the command sets the ip address to 0.0.0.0.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |                            |

| <b>Note</b>               | <ul style="list-style-type: none"> <li>• The no form of the command does not affect the mask</li> <li>• The subnets of different Proxy-ARP interfaces must not overlap or conflict with one another</li> <li>• If the IP address is set to 0.0.0.0 traffic is not forwarded by the Proxy-ARP. The IP address must be set before Ethernet-InfiniBand or InfiniBand-Ethernet traffic is passed.</li> <li>• When Proxy-ARP HA is enabled, the command is accessible from VIP. When Proxy-ARP HA is disabled, the command is accessible from the box management interface.</li> </ul> |                            |

## ip netmask

**ip netmask <mask>**

**no ip netmask**

Sets mask length for the IP address.

The no form of the command resets this parameter to its default value.

## ip vlan

**ip vlan <vlan-id>**

**no ip vlan**

Sets the VLAN number.

The no form of the command deletes the VLAN.

## ip pkey

**ip pkey <pkey>**  
**no ip pkey**

Sets the PKEY number (InfiniBand partition).  
 The no form of the command deletes the PKEY.

Trying to map the same VLAN/PKEY to a different Proxy-ARP interface results in an error message.</li> <li>If Proxy-ARP VIP is used this command is applicable via the VIP only.</li> </ul> |                                                                                                                       |

## ip route

**ip route** <ip-address/prefix> <next-hop-ip-address>  
**no ip route** [<ip-address/prefix>]

Adds a static route via this interface.

The no form of the command deletes a specified IP route or all IP routes for this interface.

## ip route default

**ip route default <next-hop-ip-address>**  
**no ip route default <next-hop-ip-address>**

Adds a default static route via this interface.  
 The no form of the command deletes the default static route.

## ha table-update-interval

**ha table-update-interval <seconds>**

**no ha table-update-interval**

Sets the time the standby table is considered valid.

The no form of the command resets the parameter to its default value.

| <b>Note</b>               | If Proxy-ARP VIP is used, this command is applicable via VIP only.                                                      |                                  |

## ha table-fast-learn-time

**ha table-fast-learn-time <seconds>**

**no ha table-fast-learn-time**

Sets the time a new master (after the previous master failed) waits before forwarding the load balancing vector to the other (non-master) nodes in the system.

The no form of the command resets the parameter to its default value.

## ha master-election-learn-interval

**ha master-election-learn-interval <seconds>**

**no ha master-election-learn-interval**

Sets the time a new Proxy-ARP group master stays in learning mode waiting for an advertisement to be received.

The no form of the command resets the parameter to its default value.

## ha advertisement-interval

**ha advertisement-interval <seconds>**

**no ha advertisement-interval**

Sets the time between keepalive messages (sent by the standby node) and master advertisement messages (sent by the master node).

The no form of the command resets the parameter to its default value.

## ha table-learn-time

**ha table-learn-time <seconds>**

**no ha table-learn-time**

Sets the time a new master (when no previous master is known) waits before forwarding the load balancing vector to the other (non-master) nodes in the system. The no form of the command resets the parameter to its default value.

## ha keep-alive-loss-threshold

**ha keep-alive-loss-threshold <value>**

**no ha keep-alive-loss-threshold**

Sets the number of lost keep alive messages in the keep alive loss interval that cause an alarm to be generated.

The no form of the command resets the parameter to its default value.

## ha keep-alive-loss-interval

**ha keep-alive-loss-interval <seconds>**

**no ha keep-alive-loss-interval**

Sets the time interval during which lost keepalive messages (more than what is configured in “ha keep-alive-loss-threshold”) trigger an alarm.

The no form of the command resets the parameter to its default value.

## ha host-list-diff-update-interval

**ha host-list-diff-update-interval <seconds>**

**no ha host-list-diff-update-interval**

Sets the time to wait after receiving a new host before sending a host list update message to the master.

The no form of the command resets the parameter to its default value.

## ha host-list-update-interval

**ha host-list-update-interval <seconds>**

**no ha host-list-update-interval**

Sets the number of seconds non-master nodes send their full host list to the master.  
The no form of the command resets the parameter to its default value.

## ha member priority

**ha member <hostname> priority <value>**

**no ha member <hostname> priority**

Sets the master election priority for member when servicing the Proxy-ARP interface. The no form of the command resets the parameter to its default value.

## ip multicast

**ip multicast <ipv4-address>**  
**no ip multicast [<ipv4-address>]**

Adds a multicast group to a Proxy-ARP instance.  
 The no form of the command deletes a specified multicast group from a Proxy-ARP instance or all multicast groups that Proxy-ARP instance belongs to.

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                                                                                                                                                                                                        |

## show interfaces proxy-arp ha ip arp

**show interfaces proxy-arp <pra-id> ha ip arp [designated]**

Displays the current ARP table of all members of this Proxy-ARP instance.

| Syntax Description | pra-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     | Proxy-ARP ID                                                                         |                               |      |                  |         |             |             |                   |              |             |            |                         |                               |             |            |                         |              |             |            |                         |              |             |            |                         |              |             |            |                         |              |             |            |                         |              |             |            |                         |              |              |            |                         |              |

## show interfaces proxy-arp ha designated-member

**show interfaces proxy-arp <pra-id> ha designated-member <Ethernet-IP> <InfiniBand-IP>**

Calculates which member of this Proxy-ARP instance handles the traffic between the given Ethernet IP and the given InfiniBand IP.

| Note               | This command is applicable from the VIP only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |                   |

## Appendix A: MEX6200 System

### A.1 MEX6200 Overview

The MEX6200 is a 3R WDM transponder, available as part of the MetroX® MTX62x0 family. It can multiplex several client signals (services) on a single fiber, each with a different wavelength, and transport them over a long distance. It is typically deployed as customer premises equipment (CPE) in enterprise campus environments and in central offices.

MEX6200 is available with 16 link ports forming up to 8 high-speed transponders that can serve lower-rate client signals of 10Gb/s.

MEX6200 is a highly integrated device that can incorporate MUX/DEMUX, Erbium Doped Fiber Amplifier (EDFA), and Dispersion Compensation Module (DCM) modules, to ensure data transmission to distances of up to 80km.

MEX6200 provides uplink 1+1 facility protection for the line ports. It also supports an optional Optical Switch that provides 1+1 facility protection for point-to-point topology.

### A.2 Getting Started

This section describes the prerequisites and the procedure required to get the MetroX system.

Be sure to follow the installation instructions in the Quick Start Guide packaged within the MetroX bundle's box.

**Figure 43: MetroX Connectivity to Switch**

Be sure not to close TCP ports 81 and 82 in your network. Those ports are used for HTTP and HTTPs connection.

➤ **To access the MEX6200 webpage:**

**Step 1.** Navigate to the MetroX's WebUI.

**Step 2.** Go to Ports tab.

**Step 3.** Click the MEX6200 sidebar tab to reach the MEX6200 WebUI page.

**Figure 44: MetroX Ports Tab Sidebar**

**Step 4.** Enable the needed link ports via the WebUI by going to each port's configuration tab and clicking on the "Admin Up" button.

The following figure shows an example of the buttons used for performing operations in the Web application.

**Figure 45: MEX6200 Item Buttons**

The buttons displayed vary according to the configuration. For example, if MEX6200 does not have an EDFA module installed, the EDFA button is disabled.

The Item buttons displayed also vary according to the context of the window. For example, the FAN button is disabled in the Fault window because no faults are defined for this unit.

On the left side of the WebUI you can find the sidebar buttons.

**Figure 46: Sidebar Buttons**

## A.3 Fault Management

This chapter describes the fault management of MEX6200, which is used to localize and identify problems in the network incorporating WDM extension units.

### A.3.1 Alarms

MEX6200 keeps a list of the alarms currently detected on the system. When an alarm is detected, an “Alarm Rise” event is generated and the alarm is added to the list. When an “Alarm Clear” is detected, the alarm is removed from the list.

The following information is stored for each alarm:

- Date and Time – the date and time when the alarm was detected.
- Source – entity that caused the alarm.
- Severity – severity of the alarm.
- Type – type of the alarm.
- Service Affecting – Yes or No according to the alarm impact.

### A.3.2 Events

MEX6200 continuously monitors the traffic signals and other exceptional conditions. Whenever such conditions occur, MEX6200 generates a time stamped event message and sends it as an SNMP notification to the registered management systems. MEX6200 logs the history of the last 512 events in a cyclic buffer that can be browsed by the Web application or by SNMP management systems.

In addition, the events and audit messages are printed in the system log files of MEX6200, which can be exported to a text file for offline viewing.

MEX6200 provides the following events:

- Alarm Rise: Alarms are standing faults. They are raised after a configurable stabilization period of several seconds. These events are generated when a new alarm occurs.
- Alarm Clear: Alarms are standing faults. They are cleared after a configurable stabilization period of several seconds. These events are generated when an alarm is cleared.
- Link Up: These are standard SNMP events that are generated when the operational status of a port is changed from Down to Up.
- Link Down: These are standard SNMP events that are generated when the operational status of a port is changed from Up to Down.
- Cold Restart: These are standard SNMP events that are generated after a Cold Restart to the node.
- Warm Restart: These are standard SNMP events that are generated after a Warm Restart to the node.
- Test Status Changed: These events are generated when the loopback or PRBS test status of a port is changed.
- Protection Switching Event: These events are generated when protection switching occurs.
- Inventory Change: These events are generated when the node inventory is changed.
- Unsolicited Event: These events are generated when an exceptional event occurs.

- **Configuration Change:** These events are generated when the node configuration is changed.

The MEX6200 generates an event when the configuration of a node is explicitly changed by the user and stores the event in the Configuration Changes log for auditing.

### A.3.3 Alarm and Event Messages

This appendix describes the possible alarm and event messages.

The following table lists the MEX6200's alarm messages and explains their interpretation and/or corrective measures.

**Table 57 - Alarm Messages**

| Source               | Message                             | Interpretation/Corrective Measures                                                                                                                                                                                              |
|----------------------|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PSU1/PSU2            | Power Supply Failure                | Replace the faulty PSU.                                                                                                                                                                                                         |
| PSU1/PSU2            | Power Failure – Low Voltage         | Replace the faulty PSU.                                                                                                                                                                                                         |
| FAN                  | Fan Failure                         | The internal cooling fan of the device does not operate. Replace the FAN unit as soon as possible.                                                                                                                              |
| System               | Hardware Failure                    | A technical failure has been detected. Replace the device.                                                                                                                                                                      |
| System               | Database Restore Failed             | Failed to update the system configuration.                                                                                                                                                                                      |
| System               | Database Restore in Progress        | Failed to update the system configuration.                                                                                                                                                                                      |
| System               | Cold Restart Required: FPGA Changed | After a warm restart, the FPGA version is not consistent with the software version. A cold restart is required.                                                                                                                 |
| System               | Software Upgrade Failed             | The downloaded software is corrupted. Reload the software.                                                                                                                                                                      |
| System               | Network Time Protocol Failure       | SNTP timing protocol failure. Check the IP connection to the NTP servers.                                                                                                                                                       |
| External Input Alarm | (As configured)                     | The External Input Alarm is active.                                                                                                                                                                                             |
| GbE (Copper)         | Ethernet Link Failure               | Check the Auto Negotiation parameters.                                                                                                                                                                                          |
| Ethernet             | Loss of Synchronization             | Loss of Synchronization has been detected on the data links. Check that the input signal rate is correct.                                                                                                                       |
| Optics               | Optics Removed                      | The optical module has been removed. Insert an optical module or shut the port down.                                                                                                                                            |
| Optics               | Optics Loss of Light                | A Loss of Light indication has been received in regards to the specific optical module. The optical power of the received signal is below the minimum power level. Check the fiber connection and/or clean the fiber connector. |
| Optics               | Optics Transmission Fault           | The transceiver is not transmitting. Replace the optical module.                                                                                                                                                                |

**Table 57 - Alarm Messages**

| Source | Message                                      | Interpretation/Corrective Measures                                                                                                                  |
|--------|----------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Optics | Optics Hardware Failure                      | A hardware fault was detected in the optical module. Replace the optical module.                                                                    |
| Optics | Optics TX Loss of Lock                       | TX CDR Loss of lock.                                                                                                                                |
| Optics | Optics High Transmission Power               | The transmission power of the optical module is above its specification.                                                                            |
| Optics | Optics Low Transmission Power                | The transmission power of the optical module is below its specification.                                                                            |
| Optics | Optics High Temperature                      | The temperature inside the optical module is above its specification.                                                                               |
| Optics | Optics Low Temperature                       | The temperature inside the optical module is below its specification.                                                                               |
| Optics | Optics High Reception Power                  | The incoming signal into the optical module is too high. An attenuation of the input signal is required.                                            |
| Optics | Optics Low Reception Power                   | The incoming signal into the optical module is too low.                                                                                             |
| Optics | Optics High Temperature                      | The temperature inside the optical module is above its specification.                                                                               |
| Optics | Optics Low Temperature                       | The temperature inside the optical module is below its specification.                                                                               |
| Optics | Optics High Laser Wavelength                 | The laser wavelength exceeds the high alarm level.                                                                                                  |
| Optics | Optics Low Laser Wavelength                  | The laser wavelength exceeds the low alarm level.                                                                                                   |
| Optics | Optics Loss Propagation                      | The laser was shut down due to a problem on the interface of the port mate.                                                                         |
| Optics | Optics Bit Rate Mismatch                     | The inserted optical module has a mismatch problem due to the wrong rate or type. Replace the optical module or update the configured service type. |
| Optics | Unauthorized Optics Inserted and is Shutdown | The inserted optical module is unauthorized for use. Replace the optical module with an authorized optical module.                                  |
| EDFA   | EDFA Gain                                    | The EDFA gain is out of acceptable range.                                                                                                           |
| EDFA   | EDFA Hardware failure                        | The interface does not respond.                                                                                                                     |
| EDFA   | EDFA Temperature                             | The EDFA temperature is out of acceptable range.                                                                                                    |
| EDFA   | EDFA Loss of Light                           | No signal is detected.                                                                                                                              |
| EDFA   | EDFA Receive Power Out of Bound              | The receive signal is out of acceptable range. Check the optical power of the EDFA client signals. Use attenuation if required.                     |

**Table 57 - Alarm Messages**

| Source | Message                          | Interpretation/Corrective Measures                                                                  |
|--------|----------------------------------|-----------------------------------------------------------------------------------------------------|
| EDFA   | EDFA Transmit Power Out of Bound | The transmit signal is out of acceptable range. Check the optical power of the EDFA client signals. |
| EDFA   | EDFA Down                        | Closed the EDFA output upon loss of input. Check the EDFA client signals.                           |
| EDFA   | EDFA Eye Safety                  | Hazard. No fiber is connected to the port.                                                          |

The following table lists the configuration event messages generated by the MEX6200 and explains their interpretation.

**Table 58 - Configuration Event Messages**

| Source       | Message                    | Interpretation                                                    |
|--------------|----------------------------|-------------------------------------------------------------------|
| System       | Change date                | The system date or time has changed.                              |
| System       | Restore provisioning       | A new configuration file has been loaded.                         |
| System       | Change IP                  | The IP of the node has changed.                                   |
| System       | Configuration change       | The system configuration was changed.                             |
| System       | Alarm cut-off              | The Alarm Cut-off has been operated.                              |
| System       | Add user                   | A new user was added.                                             |
| System       | Delete user                | A user was deleted.                                               |
| System       | Delete routing entry       | A routing entry was deleted from the system Static Routing table. |
| System       | Software Upgrade           | Software Upgrade has been performed.                              |
| Port         | Admin Down                 | Admin Down has been performed for the port.                       |
| Port         | Admin Up                   | Admin Up has been performed for the port.                         |
| Link Port    | Provisioning change        | The provisioning of the port has changed.                         |
| Link Port    | Test Operated              | A test has been operated.                                         |
| Link Port    | Facility Loopback Released | A test has been released.                                         |
| Link Port    | Reset PM counters          | Performance monitoring counters have been reset.                  |
| Service Port | Create APS                 | An APS was created for the service port.                          |
| Service Port | Remove APS                 | The APS for the service port has been removed.                    |
| Service Port | APS command                | An APS command was issued.                                        |
| Service Port | APS clear command          | An APS command was cleared.                                       |

The following table lists the other event messages generated by MEX6200 and explains their interpretation.

**Table 59 - Other Event Messages**

| Event Type         | Source           | Message                            | Interpretation                                                                   |
|--------------------|------------------|------------------------------------|----------------------------------------------------------------------------------|
| Inventory Changed  | PSU, FAN, Optics | Inventory Changed                  | The node inventory has changed. A component was inserted or removed.             |
| Switchover         | Port             | APS Switch Over                    | A protection switching event has occurred.                                       |
| Test               | Link Port        | Test Mode changed                  | The link port test mode has changed.                                             |
| ALS Status Changed | Port             | ALS Laser occurred                 | The automatic laser shutdown was activated/deactivated.                          |
| Optical Power Drop | Link port        | Power Level Drop                   | The Rx power of the port has been dropped by more than 2 dB since last interval. |
| Dying Gasp         | System           | Remote Unit Power Failure occurred | A remote unit had a power failure.                                               |
| Software Upgrade   | System           | Software Upgrade occurred          | The software upgrade operation has been completed.                               |

## A.4 Configuration Management

Table 60 provides the possible means of configuring the MEX6200.

**Table 60 - Configuration Options of the MEX6200**

| Tab                                  | Description                                                                                                                                                                                                                                  |
|--------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| System Configuration                 | Use the System Configuration window to configure general system parameters, view system inventory, configure SNTP parameters, configure IP addresses and static routing, configure SNMP parameters and traps and configure syslog servers.   |
| Link Port Configuration              | Use the Link Port Configuration window to configure the link port, configure the SFP/SFP+ module, configure ALS for a link port, and configure the APS for a link port (not available when the optional optical switch module is installed). |
| Management Port Configuration Gray   | Use the Management Port Configuration window to configure management ports and enable/disable them, configure the SFP module, and configure ALS for a management port.                                                                       |
| Ethernet Port Configuration          | Use the Ethernet Port Configuration window to configure the Ethernet port status and parameters.                                                                                                                                             |
| MUX/DEMUX Configuration Only see MUX | Use the MUX/DEMUX Configuration window to display the wavelengths of the uplink channels of MEX6200.                                                                                                                                         |
| EDFA Configuration Gray              | Use the EDFA Configuration window to configure the EDFA module and enable/disable the module.                                                                                                                                                |

| COM Port Configuration<br>Gray | Use the COM Port Configuration window to configure a COM port and enable/disable the port, configure APS for a COM port. |
| PSU Configuration              | Use the PSU Configuration window to view information about the power supply units currently installed in the system.     |
| Fan Unit Configuration         | Use the Fan Unit Configuration window to view information about the fan unit currently installed in the system.          |

## A.5 Performance Monitoring

MEX6200 provides port performance monitoring for link ports 1-16.

Use the Link Port Performance Monitoring window to view link port performance monitoring.

**Figure 47: Link Port Performance Monitoring Window**

➤ **To open the Link Port Performance Monitoring window:**

**Step 1.** Click Performance.

**Step 2.** Click a Port button to select the port.

The appropriate Link Port Performance Monitoring window opens.

### A.5.1 Native Signal

Use the Link Port Performance Monitoring tab to view link port native signal performance monitoring.

**Figure 48: Native Signal Performance Monitoring**

**Port 1 Performance Monitoring**

PM Period:  Type:

| Interval                  | Errors | Errored Seconds | Severely Errored Seconds | Unavailable Seconds | Valid        | Reset                                |
|---------------------------|--------|-----------------|--------------------------|---------------------|--------------|--------------------------------------|

Refresh every:  seconds

➤ **To view native signal performance monitoring:**

**Step 1.** Click a Port button to select the link port.

The appropriate Link Port Performance Monitoring tab opens displaying the link port performance monitoring. The fields are explained in the following table. The counters are read only.

**Step 2.** From the PM Period drop-down list, select the interval.

**Step 3.** From the Type drop-down list, select Native Signal.

**Step 4.** Click Get PM.

The performance monitoring counters are updated.

**Step 5.** Export the PM information to a file:

1. Click Export to File.

The Opening table.csv dialog box appears.

2. Click Save File.

3. Click OK.

**Step 6.** To set the refresh rate of the PM display:

1. In the Refresh every field, type the number of seconds that the window should refresh.

The minimum refresh rate is 2 seconds.

1. Click Start Refresh.

The information is automatically updated after the specified number of seconds.

- Step 7.** Refresh the PM display manually. Click Refresh.  
The information is updated immediately.
- Step 8.** Stop the automatic refresh of the PM display. Click Stop Refresh.  
The automatic refresh is stopped and the Refresh every field is cleared.
- Step 9.** Clear the PM counters for a specific PM interval. In the table, at the end of the interval row, click Reset.
- Step 10.** Clear PM counters for a specific port. Click Reset Port PM.
- Step 11.** Clear PM counters for all ports. Click Reset All Ports PM.

**Table 61 - Link Port Performance Monitoring Tab Parameters**

| Parameter                                               | Description                                                                       | Format/Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Valid                                                                                                                                                                                                                                          | Whether or not the performance monitoring interval has been completed, and whether or not the information is accurate. | <ul style="list-style-type: none"> <li>Partial: The measured interval has not been completed.</li> <li>Yes: The performance monitoring interval has been completed.</li> <li>No: The interval has been completed, but the performance monitoring information may not be accurate.</li> </ul> Note: The performance monitoring information may be inaccurate due to one of the following reasons: <ul style="list-style-type: none"> <li>The performance monitoring counters of the interval were reset.</li> <li>The node was reset during the interval.</li> <li>The port was set to Admin Down during the interval.</li> <li>The calendar time of the node was changed during the interval.</li> </ul> |

## A.5.2 Optical Level

Use the Link Port Performance Monitoring tab to view link port optical level performance monitoring.

**Figure 49: Optical Level Performance Monitoring**

➤ **To view optical level performance monitoring:**

**Step 1.** Click a Port button.

The appropriate Link Port Performance Monitoring tab opens displaying the displaying the link port performance monitoring. The fields are explained in the following table. The counters are read only.

**Step 2.** From the PM Period drop-down list, select the interval.

**Step 3.** From the Type drop-down list, select Optical Level.

**Step 4.** Click Get PM.

The optical level counters are updated.

**Step 5.** To export the optical level information to a file:

1. Click Export to File.

The Opening table.csv dialog box appears.

2.Click Save File.

3.Click OK.

**Step 6.** To set the refresh rate of the PM display:

1. In the Refresh every field, type the number of seconds that the window should refresh.

The minimum refresh rate is 2 seconds.

2.Click Start Refresh.

The information is automatically updated after the specified number of seconds.

**Step 7.** To refresh the PM display manually, click Refresh .

The information is updated immediately.

**Step 8.** To stop the automatic refresh of the PM display, click Stop Refresh.

The automatic refresh is stopped and the Refresh every field is cleared.

**Step 9.** To clear the optical level counters for a specific port, click Reset Port PM.

**Step 10.** To clear the optical level counters for all ports, click Reset All Ports PM.

**Table 62 - Link Port Performance Monitoring Tab Parameters**

| Parameter | Description                                       | Format/Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Rx Level dBm | The measured Rx power level during the interval (in dBm). | PM Period is set to 15 Minutes: <ul style="list-style-type: none"> <li>• Current: The measured Rx power for the current interval of 15 minutes is displayed in the first row.</li> <li>• 1 to 32: The measured Rx power for the last 32 intervals of 15 minutes is displayed in the second row to the last row of the table.</li> </ul> PM Period is set to Days: <ul style="list-style-type: none"> <li>• Untimed: The average of the measured Rx power since last reset of the system or since the last reset of the optical level counters is displayed in the first row of the table.</li> <li>• Current Day: The average of the measured Rx power since 00:00 AM of the current day is displayed in the second row of the table.</li> <li>• Previous Day: The average of the measured Rx power during the 24 hours since 00:00 AM of the previous day is displayed in the last row of the table.</li> </ul> |

## A.6 Maintenance

Use the maintenance tab to perform maintenance operations such as software upgrade, configuration management, restart and diagnostics.

[Table 63](#) describes the available system maintenance tasks.

**Table 63 - System Maintenance Options of the MEX6200**

| Tab               | Description                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Restart tab       | Use the Restart tab to Cold Restart (for major upgrade to the device software), Warm Restart (for minor upgrade of the device software), or restore to factory settings.                                                                                          |
| Log Files tab     | Use the Log Files tab to view and save System Log files.                                                                                                                                                                                                          |
| Configuration tab | Use the Configuration tab to update the system configuration with a previously saved file of system configuration, while preserving or replacing the IP addresses, or to upload the current system configuration of MEX6200 and save it to the local file system. |
| Software tab      | Use the Software tab to download software and to switch and activate a new software version.                                                                                                                                                                      |

Use the Link Port Maintenance window to perform diagnostic tests on link ports.

Use the External Alarm tab to configure the external alarm.

## A.6.1 Upgrading Software on the MEX6200

➤ *To perform software upgrade:*

- Step 1.** Click the “System” button at the top left of the WebUI page of MEX6200.
- Step 2.** Click the “Maintenance” sidebar button.
- Step 3.** Click the “Software” tab.
- Step 4.** Click the “Browse” button and locate the image to upgrade the software.
- Step 5.** Click “Download”.
- Step 6.** Reboot the MEX6200 by clicking “Switch and Cold Restart”.

**Figure 50: MEX6200 Software Upgrade Webpage**

## Appendix B: Strict Security Mode

### B.1 Overview

Strict mode is a security state of a system complying with the NIST SP 800-131A standard. Because of compatibility issues, strict mode is not the default state of the system and it should be manually set. Strict mode is based on NIST SP 800-131A document which defines cryptographically “acceptable” technologies. This document explains how to configure possible cryptographic vulnerabilities in the system to use secure technologies.

Some protocols, however, cannot be operated in a manner that complies with the standard.

### B.2 Web Certificate

Mellanox supports signature generation of sha256WithRSAEncryption, sha1WithRSAEncryption self-signed certificates, and importing certificates as text in PEM format.

➤ **To configure a default certificate:**

**Step 1.** Create a new sha256 certificate. Run:

```
switch (config) # crypto certificate name <cert name> generate self-signed hash-algorithm sha256
```

For more details and parameters refer to the command crypto certificate name in the MLNX-OS User Manual.

**Step 2.** Show crypto certificate detail. Run:

```
switch (config) # show crypto certificate detail
```

Search for “signature algorithm” in the output.

**Step 3.** Set this certificate as the default certificate. Run:

```
switch (config) # crypto certificate default-cert name <cert name>
```

➤ **To configure default parameters and create a new certificate:**

**Step 1.** Define the default hash algorithm. Run:

```
switch (config) # crypto certificate generation default hash-algorithm sha256
```

**Step 2.** Generate a new certificate with default values. Run:

```
switch (config) # crypto certificate name <cert name> generate self-signed
```

When no options are selected, the generated certificate uses the default values for each field.

To test strict mode connect to the WebUI using HTTPS and get the certificate. Search for “signature algorithm”.

There are other ways to configure the certificate to sha256. For example, it is possible to use certificate generation default hash-algorithm and then regenerate the certificate using these default values. Please refer to the MLNX-OS User Manual for further details.

It is recommended to delete browsing data and previous certificates before retrying to connect to the WebUI.

Make sure not to confuse “signature algorithm” with “Thumbprint algorithm”.

## B.3 Code Signing

Code signing is used to verify that the data in the image is not modified by any third-party. MLNX-OS supports signing the image files with SHA256, RSA2048 using GnuPG.

Strict mode is operational by default.

## B.4 SNMP

SNMPv3 supports configuring username, authentication keys and privacy keys. For authentication keys it is possible to use MD5 or SHA. For privacy keys AES or DES are to be used.

- **To configure strict mode, create a new user with HMAC-SHA1-96 and AES-128. Run:**

```
switch (config) # snmp-server user <username> v3 auth sha <password1> priv aes-128 <password2>
```

- **To verify the user in the CLI, run:**

```
switch (config) # show snmp user
```

To test strict mode, configure users and check them using the CLI, then run an SNMP request with the new users.  
For more information please refer to the MLNX-OS User Manual.

SNMPv1 and SNMPv2 are not considered to be secure. To run in strict mode, only use SNMPv3.

## B.5 SSH

The SSH server on the switch by default uses secure and unsecure ciphers, message authentication code (MAC), key exchange methods, and public key algorithm. When configuring SSH server to strict mode, the aforementioned security methods only use approved algorithms as detailed in the NIST 800-181A specification and the user can connect to the switch via SSH in secure mode only.

➤ **To enable strict security mode, run:**

```
switch (config) # ssh server security strict
```

The no form of the command disables strict security mode.

Make sure to configure the SSH server to work with minimum version 2 since 1 is vulnerable to security breaches.

➤ **To configure min-version to strict mode, run:**

```
switch (config) # ssh server min-version 2
```

Once this is done, the user cannot revert back to minimum version 1.

## B.6 HTTPS

By default, Mellanox switch supports HTTPS encryption using TLS1.0 up to TLS1.2. To work in strict mode you must configure the system to use TLS1.2. Working in TLS1.2 mode also bans MD5 ciphers which are not allowed per NIST 800-131a. In strict mode, the switch supports encryption with TLS1.2 only with the following supported ciphers:

- RSA\_WITH\_AES\_128\_CBC\_SHA256
- RSA\_WITH\_AES\_256\_CBC\_SHA256
- DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- DHE\_RSA\_WITH\_AES\_256\_CBC\_SHA256
- TLS\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_RSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_DHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_256\_GCM\_SHA384

➤ **To enable all encryption methods, run:**

```
switch (config) # web https ssl ciphers all
```

➤ **To enable only TLS ciphers (enabled by default), run:**

```
switch (config) # web https ssl ciphers TLS
```

➤ **To enable HTTPS strict mode, run:**

```
switch (config) # web https ssl ciphers TLS1.2
```

➤ **To verify which encryption methods are used, run:**

```
switch (config)# show web
Web User Interface:
 Web interface enabled: yes
 HTTP enabled: yes
 HTTP port: 80
 HTTP redirect to HTTPS: no
 HTTPS enabled: yes
 HTTPS port: 443
 HTTPS ssl-ciphers: TLS1.2
 HTTPS certificate name: default-cert
 Listen enabled: yes
 No Listen Interfaces.

 Inactivity timeout: disabled
 Session timeout: 2 hr 30 min
 Session renewal: 30 min

Web file transfer proxy:
 Proxy enabled: no

Web file transfer certificate authority:
 HTTPS server cert verify: yes
 HTTPS supplemental CA list: default-ca-list
switch (config)#
```

On top of enabling HTTPS, to prevent security breaches HTTP must be disabled.

➤ **To disable HTTP, run:**

```
switch (config)# no web http enable
```

## B.7 LDAP

By default, Mellanox switch supports LDAP encryption SSL version 3 or TLS1.0 up to TLS1.2. The only banned algorithm is MD5 which is not allowed per NIST 800-131a. In strict mode, the switch supports encryption with TLS1.2 only with the following supported ciphers:

- DHE-DSS-AES128-SHA256
- DHE-RSA-AES128-SHA256
- DHE-DSS-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- DHE-DSS-AES256-SHA256
- DHE-RSA-AES256-SHA256
- DHE-DSS-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- ECDH-ECDSA-AES128-SHA256
- ECDH-RSA-AES128-SHA256
- ECDH-ECDSA-AES128-GCM-SHA256

- ECDH-RSA-AES128-GCM-SHA256
- ECDH-ECDSA-AES256-SHA384
- ECDH-RSA-AES256-SHA384
- ECDH-ECDSA-AES256-GCM-SHA384
- ECDH-RSA-AES256-GCM-SHA384
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- AES128-SHA256
- AES128-GCM-SHA256
- AES256-SHA256
- AES256-GCM-SHA384

➤ **To enable LDAP strict mode, run:**

```
switch (config) # ldap ssl mode {start-tls | ssl}
```

Both modes operate using SSL. The difference lies in the connection initialization and the port used.

➤ **To enable all encryption methods (enabled by default), run:**

```
switch (config) # ldap ssl ciphers TLS1.2
```

➤ **To verify which encryption methods are used, run:**

```
switch (config)# show ldap
User base DN : ou=People,dc=test,dc=com
User search scope : subtree
Login attribute : uid
Bind DN : cn=manager,dc=test,dc=com
Bind password : *****
Group base DN :
Group attribute : member
LDAP version : 3
Referrals : yes
Server port : 389 (not active)
Search Timeout : 5
```

```

Bind Timeout : 5
SSL mode : ssl
Server SSL port : 636
SSL ciphers : TLS1.2
SSL cert verify : yes
SSL ca-list : default-ca-list

LDAP servers:
1: 10.134.47.5
switch (config)#

```

Please make sure that “(not active)” does not appear adjacent to the line “SSL ciphers”.

## B.8 Password Hashing

To comply with NIST 800-131a, Mellanox switches support password encryption with SHA512 algorithm.

➤ **To see the password encryption used, run:**

```

switch (config)# show usernames

```

| USERNAME | FULL NAME            | CAPABILITY | ACCOUNT STATUS                 |
|----------|----------------------|------------|--------------------------------|
| admin    | System Administrator | admin      | No password required for login |
| monitor  | System Monitor       | monitor    | Password set (SHA512)          |
| xmladmin | XML Admin User       | admin      | No password required for login |
| xmluser  | XML Monitor User     | monitor    | No password required for login |

Using default usernames and passwords or using usernames without passwords is highly not recommended.

When moving to strict mode, the password of each user must be reconfigured to a non-default value using the CLI command `username`.

For example, if you have a user ID “myuser” whose password is hashed with MD5, this user must be recreated manually using the command “`username myuser password mypassword`”. The password then is automatically hashed using SHA512.

The following output demonstrates the example above:

```

switch (config)# show usernames

```

| USERNAME | FULL NAME            | CAPABILITY | ACCOUNT STATUS                 |
|----------|----------------------|------------|--------------------------------|
| admin    | System Administrator | admin      | No password required for login |
| myuser   | System Monitor       | monitor    | Password set (MD5)             |

```

switch (config)# username myuser password mypassword
switch (config)# show usernames

```

| USERNAME | FULL NAME            | CAPABILITY | ACCOUNT STATUS                 |
|----------|----------------------|------------|--------------------------------|
| admin    | System Administrator | admin      | No password required for login |
| myuser   | System Monitor       | monitor    | Password set (SHA512)          |
