PRODUCT OVERVIEW

S3C8-SERIES MICROCONTROLLERS

Samsung's S3C8 series of 8-bit single-chip CMOS microcontrollers offers a fast and efficient CPU, a wide range of integrated peripherals, and various mask-programmable ROM sizes. Among the major CPU features are:

- Efficient register-oriented architecture
- Selectable CPU clock sources
- Idle and Stop power-down mode release by interrupt
- Built-in basic timer with watchdog function

A sophisticated interrupt structure recognizes up to eight interrupt levels. Each level can have one or more interrupt sources and vectors. Fast interrupt processing (within a minimum of four CPU clocks) can be assigned to specific interrupt levels.

S3C831B MICROCONTROLLER

The S3C831B single-chip microcontroller are fabricated using the highly advanced CMOS process. Its design is based on the powerful SAM88RC CPU core. Stop and idle (power-down) modes were implemented to reduce power consumption.

The S3C831B is a microcontroller with a 64K-byte mask-programmable ROM embedded.
The S3P831B is a microcontroller with a 64K-byte one-time-programmable ROM embedded.

Using the SAM88RC modular design approach, the following peripherals were integrated with the SAM88RC CPU core:

- Large number of programable I/O ports (Total 72 pins)
- PLL frequency synthesizer
- 16-bits intermediate frequency counter
- Two synchronous SIO modules
- Two 8-bit timer/counters
- One 16-bit timer/counter
- Low voltage reset
- A/D converter with 8 selectable input pins

OTP

The S3C831B microcontroller is also available in OTP (One Time Programmable) version, S3P831B. The S3P831B microcontroller has an on-chip 64K-byte one-time-programmable EPROM instead of masked ROM. The S3P831B is comparable to S3C831B, both in function and in pin configuration.

FEATURES

CPU

- SAM88RC CPU core

Memory

- 2576-byte internal register file (including LCD display RAM)
- 64K-byte internal program memory area

Instruction Set

- 78 instructions
- Idle and Stop instructions

72 I/O Pins

- 32 normal I/O pins
- 40 pins sharing with LCD segment signals

Interrupts

- 8 interrupt levels and 17 internal sources
- Fast interrupt processing feature

8-Bit Basic Timer

- Watchdog timer function
- 4 kinds of clock source

Timer/Counter 0

- Programmable 8-bit internal timer
- External event counter function
- PWM and capture function

Timer/Counter 1

- Programmable 8-bit interval timer
- External event counter function

Timer/Counter 2

- Programmable 16-bit interval timer
- External event counter function

Watch Timer

- Interval Time: 50ms, 0.5s, 1.0s at 4.5 MHz
- 1/1.5/3/6 kHz buzzer output selectable

Analog to Digital Converter

- 8-channel analog input
- 8-bit conversion resolution

Two 8-bit Serial I/O Interface

- 8-bit transmit/receive mode
- 8-bit receive mode
- Selectable baud rate or external clock source

PLL Frequency Synthesizer

- V_{IN} level: 300mV_{pp} (minimum)
- AMVCO range: 0.5 MHz–30 MHz (3-bit counter added)
- FMVCO range: 30 MHz–150 MHz

16-Bit Intermediate Frequency (IF) Counter

- V_{IN} level: 300mV_{pp} (minimum)
- AMIF range: 100 kHz–1 MHz
- FMIF range: 5 MHz–15 MHz

LCD Controller/Driver

- 40 segments and 4 common terminals
- 4/3/2 common and static selectable
- Internal or external resistor circuit for LCD bias

Low Voltage Reset (LVR)

- Low voltage check to make system reset
- V_{LVR} : 2.4V, 3.7 V selectable

Two Power-Down Modes

- Idle mode: only CPU clock stops
- Stop mode: system clock and CPU clock stop

Oscillation Source

- Crystal or ceramic for system clock (fx)

Instruction Execution Time

- 444 ns at 9.0 MHz (minimum)

Operating Temperature Range

- –25 °C to +85 °C

Operating Voltage Range

- 2.2V to 5.5V at 0.4 MHz – 4.5 MHz
- 4.0 V to 5.5 V at 0.4 MHz–9.0 MHz
- 2.5V to 3.5V, 4.5 V to 5.5 V in PLL/IFC block

Package Type

- 100-QFP-1420C, 100-TQFP-1414

ADDRESS SPACES

OVERVIEW

The S3C831B microcontroller has two types of address space:

- Internal program memory (ROM)
- Internal register file

A 16-bit address bus supports program memory operations. A separate 8-bit register bus carries addresses and data between the CPU and the register file.

The S3C831B has an internal 64-Kbyte mask-programmable ROM.

The 256-byte physical register space is expanded into an addressable area of 320 bytes using addressing modes.

A 20-byte LCD display register file is implemented.

There are 2,646 mapped registers in the internal register file. Of these, 2,576 are for general-purpose. (This number includes a 16-byte working register common area used as a "scratch area" for data operations, ten 192-byte prime register areas, and ten 64-byte areas (Set 2)). Thirteen 8-bit registers are used for the CPU and the system control, and 57 registers are mapped for peripheral controls and data registers. Ten register locations are not mapped.

PROGRAM MEMORY (ROM)

Program memory (ROM) stores program codes or table data. The S3C831B has 64K bytes internal mask-programmable program memory.

The first 256 bytes of the ROM (0H–0FFH) are reserved for interrupt vector addresses. Unused locations in this address range can be used as normal program memory. If you use the vector address area to store a program code, be careful not to overwrite the vector addresses stored in these locations.

The ROM address at which a program execution starts after a reset is 0100H.

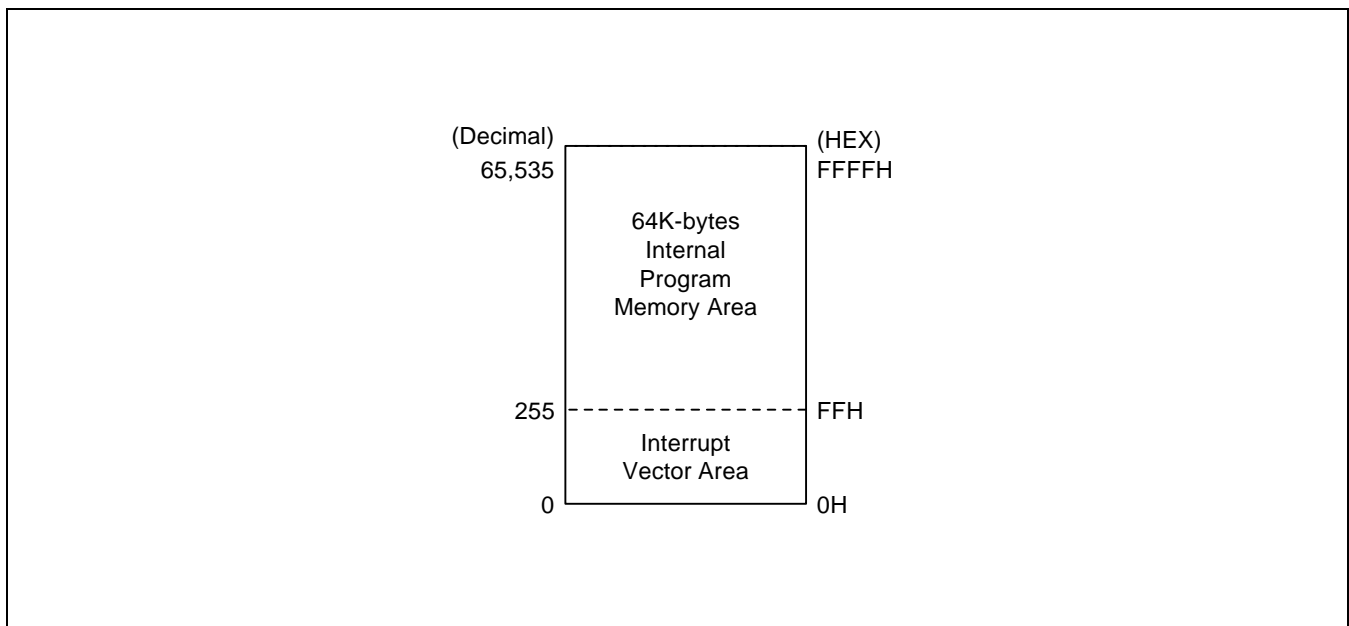

Figure 2-1. Program Memory Address Space

REGISTER ARCHITECTURE

In the S3C831B implementation, the upper 64-byte area of register files is expanded two 64-byte areas, called *set 1* and *set 2*. The upper 32-byte area of set 1 is further expanded two 32-byte register banks (bank 0 and bank 1), and the lower 32-byte area is a single 32-byte common area.

In case of S3C831B the total number of addressable 8-bit registers is 2,646. Of these 2,646 registers, 13 bytes are for CPU and system control registers, 57 bytes are for peripheral control and data registers, 16 bytes are used as a shared working registers, and 2,560 registers are for general-purpose use, page 0-page 9 (including 20 bytes for LCD display registers).

You can always address set 1 register locations, regardless of which of the ten register pages is currently selected. Set 1 locations, however, can only be addressed using register addressing modes.

The extension of register space into separately addressable areas (sets, banks, and pages) is supported by various addressing mode restrictions, the select bank instructions, SB0 and SB1, and the register page pointer (PP).

Specific register types and the area (in bytes) that they occupy in the register file are summarized in Table 2–1.

Table 2-1. S3C831B Register Type Summary

Register Type	Number of Bytes
General-purpose registers (including the 16-byte common working register area, ten 192-byte prime register area (including LCD data registers), and ten 64-byte set 2 area).	2,576
CPU and system control registers	13
Mapped clock, peripheral, I/O control, and data registers	57
Total Addressable Bytes	2,646

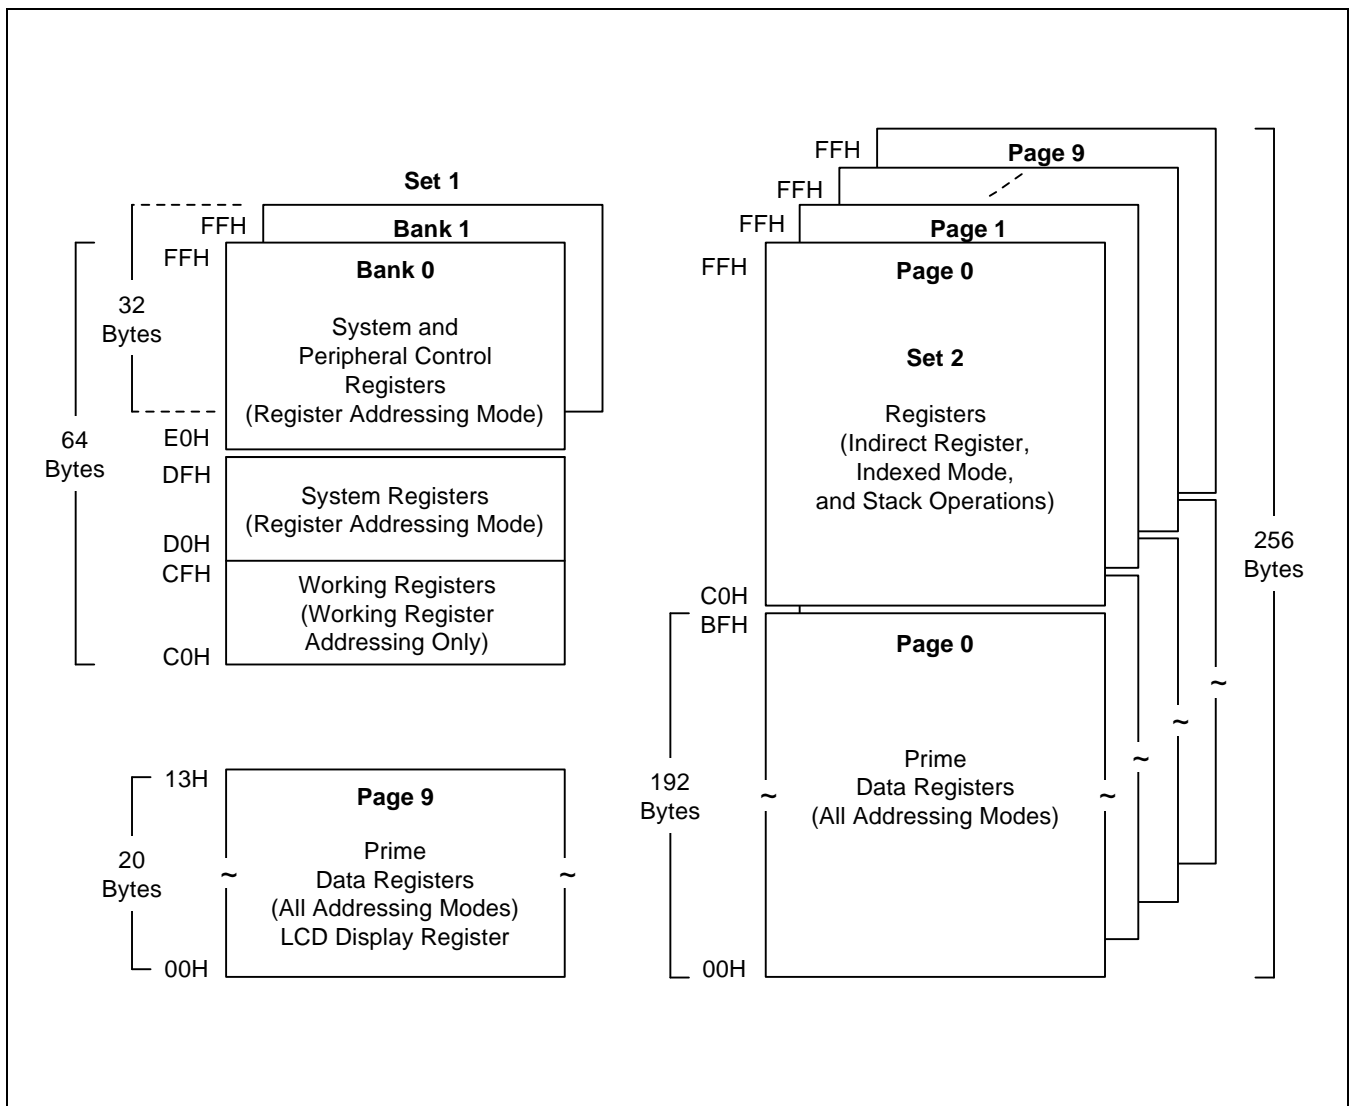

Figure 2-2. Internal Register File Organization

REGISTER PAGE POINTER (PP)

The S3C8-series architecture supports the logical expansion of the physical 256-byte internal register file (using an 8-bit data bus) into as many as 16 separately addressable register pages. Page addressing is controlled by the register page pointer (PP, DFH). In the S3C831B microcontroller, a paged register file expansion is implemented for LCD data registers, and the register page pointer must be changed to address other pages.

After a reset, the page pointer's source value (lower nibble) and the destination value (upper nibble) are always "0000", automatically selecting page 0 as the source and destination page for register addressing.

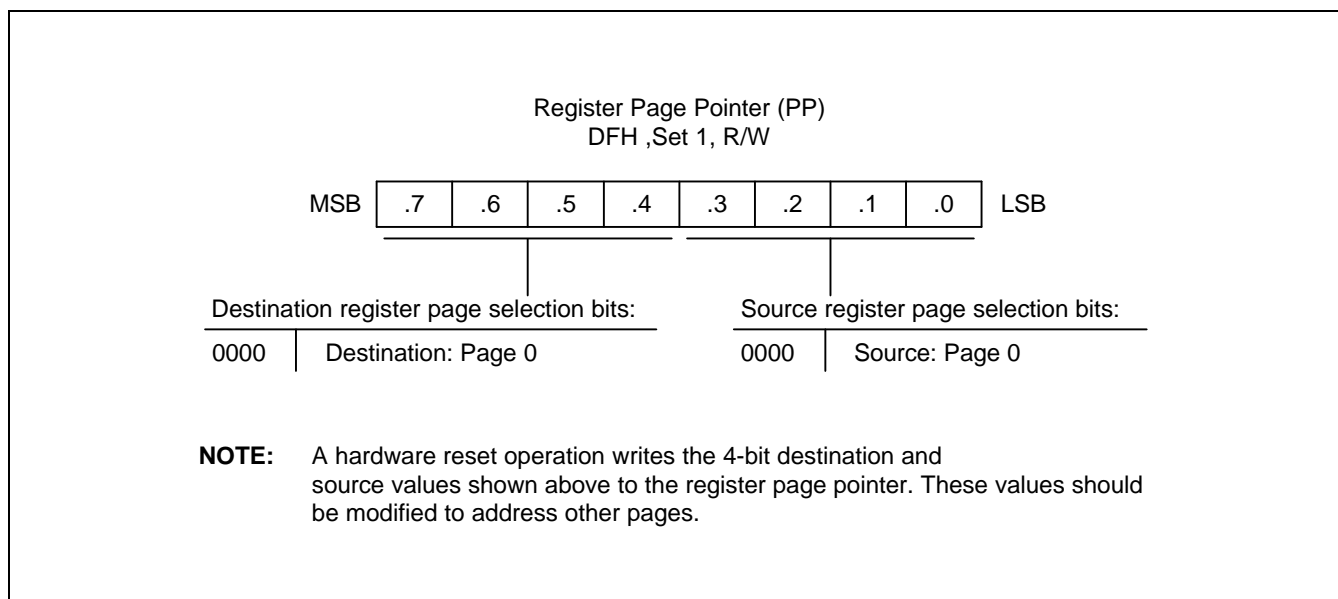

Figure 2-3. Register Page Pointer (PP)

PROGRAMMING TIP — Using the Page Pointer for RAM clear (Page 0, Page 1)

	LD PP,#00H	; Destination ← 0, Source ← 0
	SRP #0C0H	
	LD R0,#0FFH	; Page 0 RAM clear starts
RAMCL0	CLR @R0	
	DJNZ R0,RAMCL0	
	CLR @R0	; R0 = 00H
	LD PP,#10H	; Destination ← 1, Source ← 0
	LD R0,#0FFH	; Page 1 RAM clear starts
RAMCL1	CLR @R0	
	DJNZ R0,RAMCL1	
	CLR @R0	; R0 = 00H

NOTE: You should refer to page 6-39 and use DJNZ instruction properly when DJNZ instruction is used in your program.

REGISTER SET 1

The term *set 1* refers to the upper 64 bytes of the register file, locations C0H–FFH.

The upper 32-byte area of this 64-byte space (E0H–FFH) is expanded two 32-byte register banks, *bank 0* and *bank 1*. The set register bank instructions, SB0 or SB1, are used to address one bank or the other. A hardware reset operation always selects bank 0 addressing.

The upper two 32-byte areas (bank 0 and bank 1) of set 1 (E0H–FFH) contains 57 mapped system and peripheral control registers. The lower 32-byte area contains 16 system registers (D0H–DFH) and a 16-byte common working register area (C0H–CFH). You can use the common working register area as a “scratch” area for data operations being performed in other areas of the register file.

Registers in set 1 locations are directly accessible at all times using Register addressing mode. The 16-byte working register area can only be accessed using working register addressing (For more information about working register addressing, please refer to Chapter 3, “Addressing Modes.”)

REGISTER SET 2

The same 64-byte physical space that is used for set 1 locations C0H–FFH is logically duplicated to add another 64 bytes of register space. This expanded area of the register file is called set 2. For the S3C831B, the set 2 address range (C0H–FFH) is accessible on pages 0-9.

The logical division of set 1 and set 2 is maintained by means of addressing mode restrictions. You can use only Register addressing mode to access set 1 locations. In order to access registers in set 2, you must use Register Indirect addressing mode or Indexed addressing mode.

The set 2 register area of page 0 is commonly used for stack operations.

PRIME REGISTER SPACE

The lower 192 bytes (00H–BFH) of the S3C831B's ten 256-byte register pages is called *prime register area*. Prime registers can be accessed using any of the seven addressing modes (see Chapter 3, "Addressing Modes.")

The prime register area on page 0 is immediately addressable following a reset. In order to address prime registers on pages 0, 1, 2, 3, 4, 5, 6, 7, 8, or 9 you must set the register page pointer (PP) to the appropriate source and destination values.

Figure 2-4. Set 1, Set 2, Prime Area Register, and LCD Data Register Map

WORKING REGISTERS

Instructions can access specific 8-bit registers or 16-bit register pairs using either 4-bit or 8-bit address fields. When 4-bit working register addressing is used, the 256-byte register file can be seen by the programmer as one that consists of 32 8-byte register groups or "slices." Each slice comprises of eight 8-bit registers.

Using the two 8-bit register pointers, RP1 and RP0, two working register slices can be selected at any one time to form a 16-byte working register block. Using the register pointers, you can move this 16-byte register block anywhere in the addressable register file, except the set 2 area.

The terms slice and block are used in this manual to help you visualize the size and relative locations of selected working register spaces:

- One working register *slice* is 8 bytes (eight 8-bit working registers, R0–R7 or R8–R15)
- One working register *block* is 16 bytes (sixteen 8-bit working registers, R0–R15)

All the registers in an 8-byte working register slice have the same binary value for their five most significant address bits. This makes it possible for each register pointer to point to one of the 24 slices in the register file. The base addresses for the two selected 8-byte register slices are contained in register pointers RP0 and RP1.

After a reset, RP0 and RP1 always point to the 16-byte common area in set 1 (C0H–CFH).

Figure 2-5. 8-Byte Working Register Areas (Slices)

USING THE REGISTER POINTS

Register pointers RP0 and RP1, mapped to addresses D6H and D7H in set 1, are used to select two movable 8-byte working register slices in the register file. After a reset, they point to the working register common area: RP0 points to addresses C0H–C7H, and RP1 points to addresses C8H–CFH.

To change a register pointer value, you load a new value to RP0 and/or RP1 using an SRP or LD instruction. (see Figures 2-6 and 2-7).

With working register addressing, you can only access those two 8-bit slices of the register file that are currently pointed to by RP0 and RP1. You cannot, however, use the register pointers to select a working register space in set 2, C0H–FFH, because these locations can be accessed only using the Indirect Register or Indexed addressing modes.

The selected 16-byte working register block usually consists of two contiguous 8-byte slices. As a general programming guideline, it is recommended that RP0 point to the "lower" slice and RP1 point to the "upper" slice (see Figure 2-6). In some cases, it may be necessary to define working register areas in different (non-contiguous) areas of the register file. In Figure 2-7, RP0 points to the "upper" slice and RP1 to the "lower" slice.

Because a register pointer can point to either of the two 8-byte slices in the working register block, you can flexibly define the working register area to support program requirements.

PROGRAMMING TIP — Setting the Register Pointers

SRP	#70H	; RP0 ← 70H, RP1 ← 78H
SRP1	#48H	; RP0 ← no change, RP1 ← 48H,
SRP0	#0A0H	; RP0 ← A0H, RP1 ← no change
CLR	RP0	; RP0 ← 00H, RP1 ← no change
LD	RP1, #0F8H	; RP0 ← no change, RP1 ← 0F8H

Figure 2-6. Contiguous 16-Byte Working Register Block

Figure 2-7. Non-Contiguous 16-Byte Working Register Block

PROGRAMMING TIP — Using the RPs to Calculate the Sum of a Series of Registers

Calculate the sum of registers 80H–85H using the register pointer. The register addresses from 80H through 85H contain the values 10H, 11H, 12H, 13H, 14H, and 15 H, respectively:

SRP0	#80H	; RP0 ← 80H
ADD	R0,R1	; R0 ← R0 + R1
ADC	R0,R2	; R0 ← R0 + R2 + C
ADC	R0,R3	; R0 ← R0 + R3 + C
ADC	R0,R4	; R0 ← R0 + R4 + C
ADC	R0,R5	; R0 ← R0 + R5 + C

The sum of these six registers, 6FH, is located in the register R0 (80H). The instruction string used in this example takes 12 bytes of instruction code and its execution time is 36 cycles. If the register pointer is not used to calculate the sum of these registers, the following instruction sequence would have to be used:

ADD	80H,81H	; 80H ← (80H) + (81H)
ADC	80H,82H	; 80H ← (80H) + (82H) + C
ADC	80H,83H	; 80H ← (80H) + (83H) + C
ADC	80H,84H	; 80H ← (80H) + (84H) + C
ADC	80H,85H	; 80H ← (80H) + (85H) + C

Now, the sum of the six registers is also located in register 80H. However, this instruction string takes 15 bytes of instruction code rather than 12 bytes, and its execution time is 50 cycles rather than 36 cycles.

REGISTER ADDRESSING

The S3C8-series register architecture provides an efficient method of working register addressing that takes full advantage of shorter instruction formats to reduce execution time.

With Register (R) addressing mode, in which the operand value is the content of a specific register or register pair, you can access any location in the register file except for set 2. With working register addressing, you use a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space.

Registers are addressed either as a single 8-bit register or as a paired 16-bit register space. In a 16-bit register pair, the address of the first 8-bit register is always an even number and the address of the next register is always an odd number. The most significant byte of the 16-bit data is always stored in the even-numbered register, and the least significant byte is always stored in the next (+1) odd-numbered register.

Working register addressing differs from Register addressing as it uses a register pointer to identify a specific 8-byte working register space in the internal register file and a specific 8-bit register within that space.

Figure 2-8. 16-Bit Register Pair

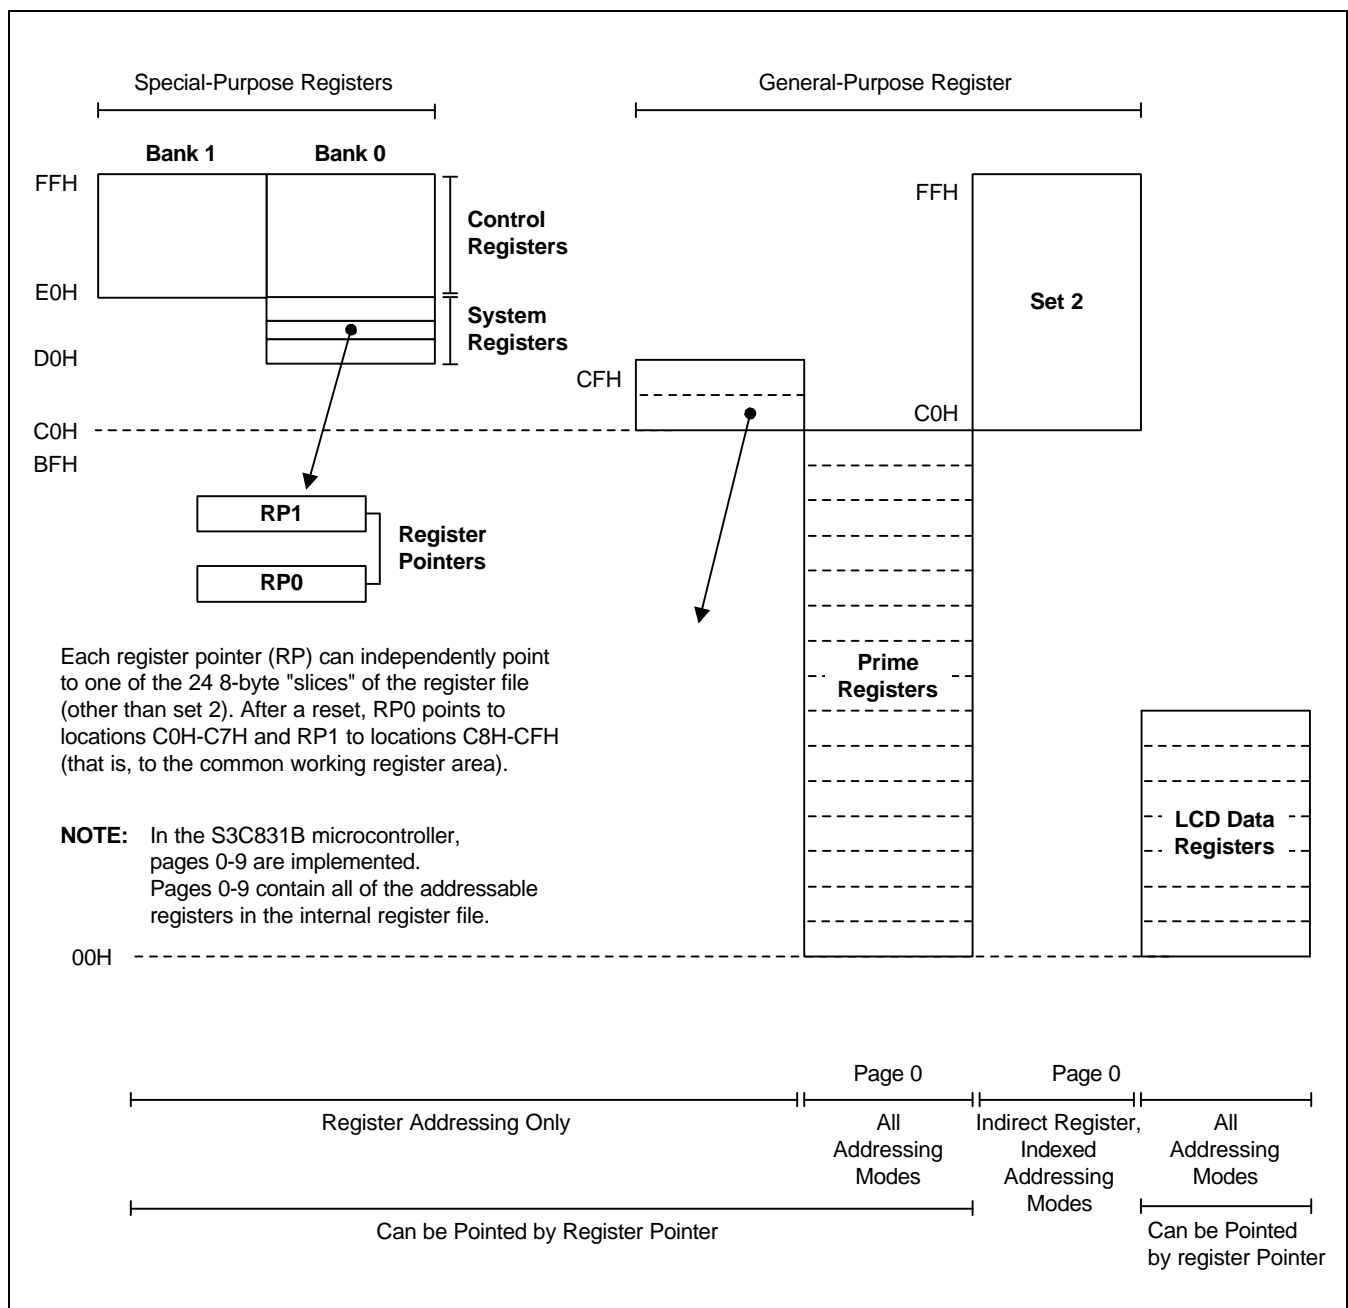

Figure 2-9. Register File Addressing

COMMON WORKING REGISTER AREA (C0H–CFH)

After a reset, register pointers RP0 and RP1 automatically select two 8-byte register slices in set 1, locations C0H–CFH, as the active 16-byte working register block:

RP0 → C0H–C7H

RP1 → C8H–CFH

This 16-byte address range is called *common area*. That is, locations in this area can be used as working registers by operations that address any location on any page in the register file. Typically, these working registers serve as temporary buffers for data operations between different pages.

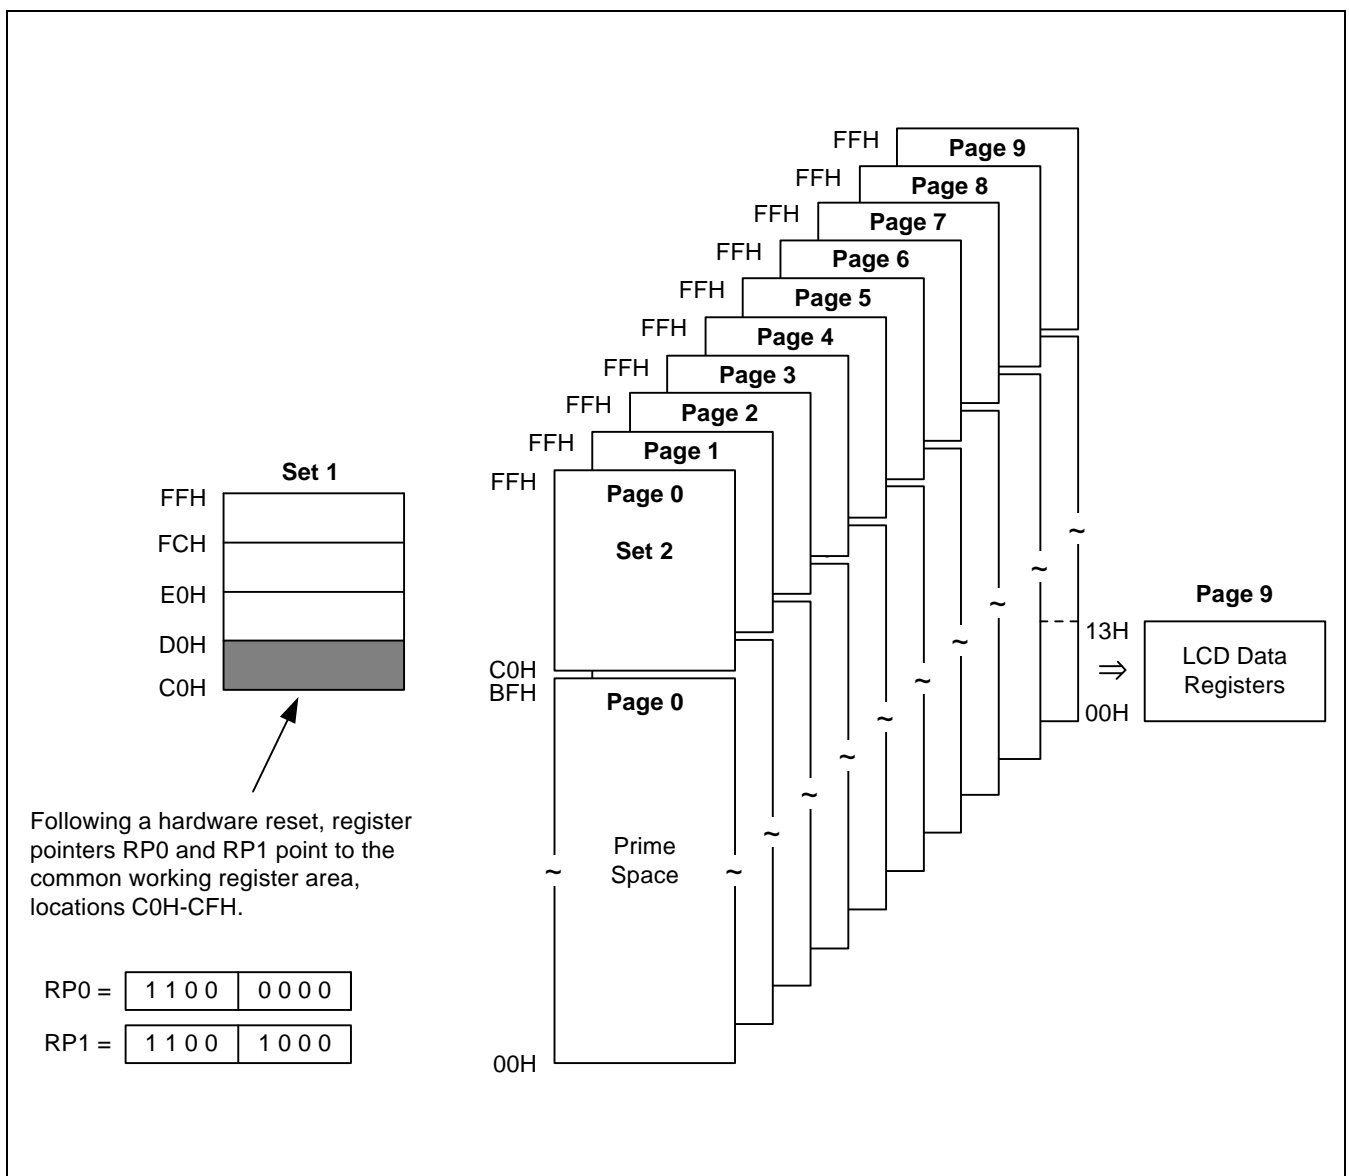

Figure 2-10. Common Working Register Area

PROGRAMMING TIP — Addressing the Common Working Register Area

As the following examples show, you should access working registers in the common area, locations C0H–CFH, using working register addressing mode only.

Examples

- LD 0C2H,40H ; Invalid addressing mode!
 Use working register addressing instead:
 SRP #0C0H
 LD R2,40H ; R2 (C2H) ← the value in location 40H
- ADD 0C3H,#45H ; Invalid addressing mode!
 Use working register addressing instead:
 SRP #0C0H
 ADD R3,#45H ; R3 (C3H) ← R3 + 45H

4-BIT WORKING REGISTER ADDRESSING

Each register pointer defines a movable 8-byte slice of working register space. The address information stored in a register pointer serves as an addressing "window" that makes it possible for instructions to access working registers very efficiently using short 4-bit addresses. When an instruction addresses a location in the selected working register area, the address bits are concatenated in the following way to form a complete 8-bit address:

- The high-order bit of the 4-bit address selects one of the register pointers ("0" selects RP0, "1" selects RP1).
- The five high-order bits in the register pointer select an 8-byte slice of the register space.
- The three low-order bits of the 4-bit address select one of the eight registers in the slice.

As shown in Figure 2-11, the result of this operation is that the five high-order bits from the register pointer are concatenated with the three low-order bits from the instruction address to form the complete address. As long as the address stored in the register pointer remains unchanged, the three bits from the address will always point to an address in the same 8-byte register slice.

Figure 2-12 shows a typical example of 4-bit working register addressing. The high-order bit of the instruction "INC R6" is "0", which selects RP0. The five high-order bits stored in RP0 (01110B) are concatenated with the three low-order bits of the instruction's 4-bit address (110B) to produce the register address 76H (01110110B).

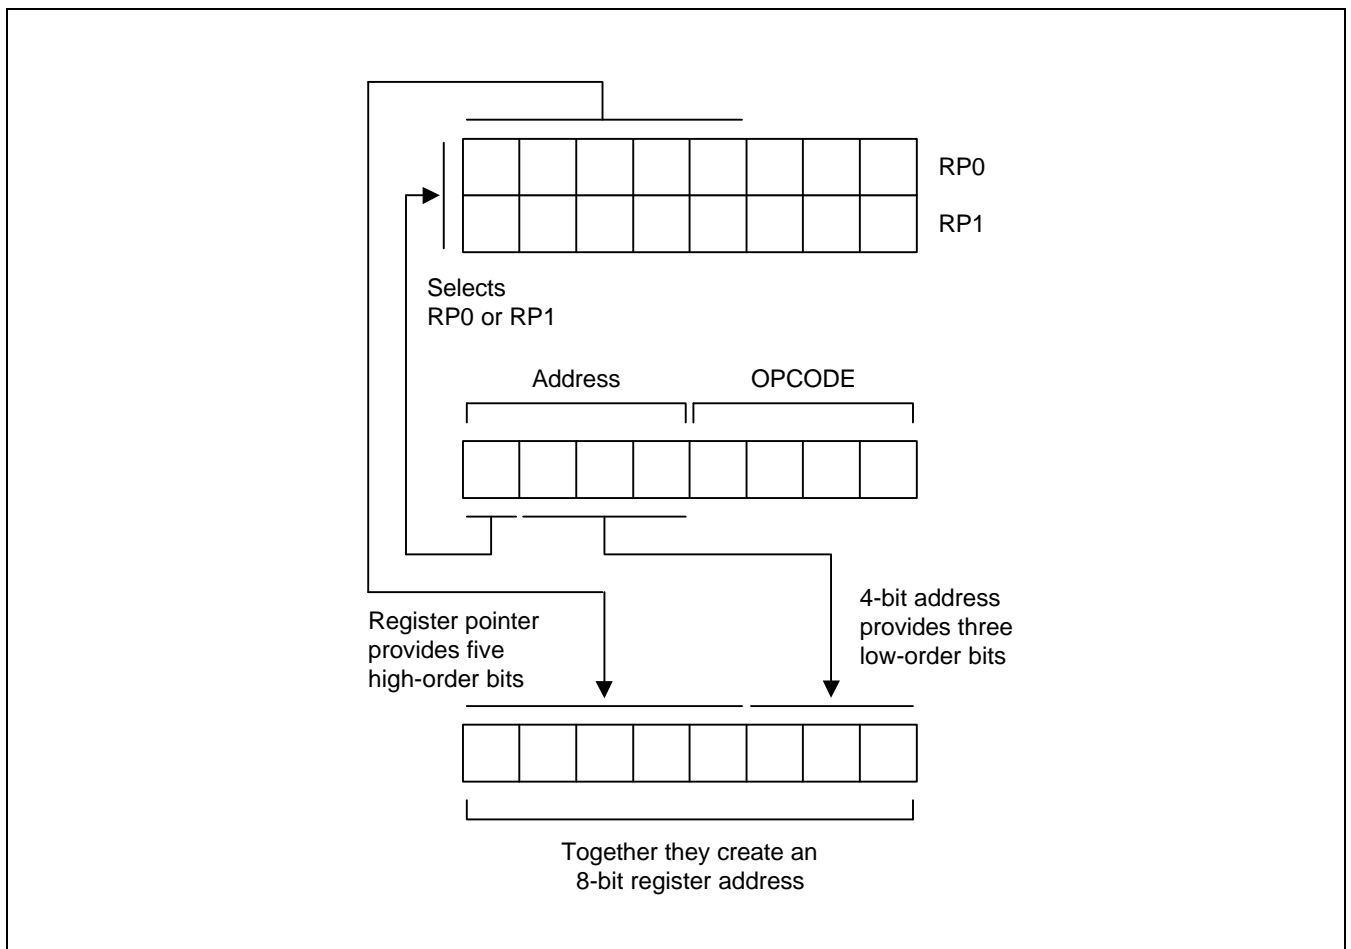

Figure 2-11. 4-Bit Working Register Addressing

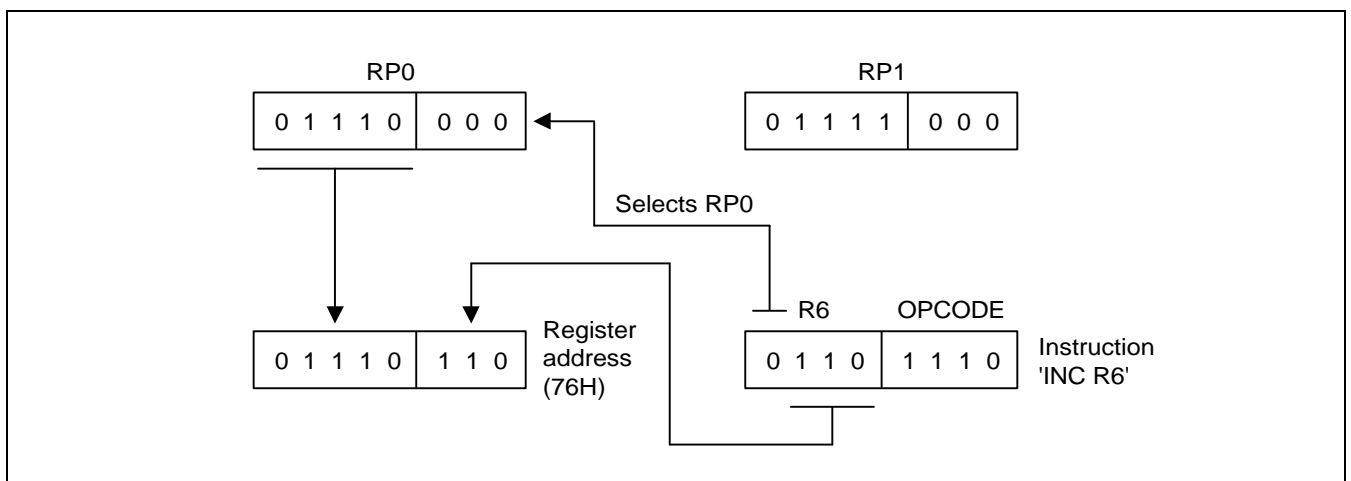

Figure 2-12. 4-Bit Working Register Addressing Example

8-BIT WORKING REGISTER ADDRESSING

You can also use 8-bit working register addressing to access registers in a selected working register area. To initiate 8-bit working register addressing, the upper four bits of the instruction address must contain the value "1100B." This 4-bit value (1100B) indicates that the remaining four bits have the same effect as 4-bit working register addressing.

As shown in Figure 2-13, the lower nibble of the 8-bit address is concatenated in much the same way as for 4-bit addressing: Bit 3 selects either RP0 or RP1, which then supplies the five high-order bits of the final address; the three low-order bits of the complete address are provided by the original instruction.

Figure 2-14 shows an example of 8-bit working register addressing. The four high-order bits of the instruction address (1100B) specify 8-bit working register addressing. Bit 4 ("1") selects RP1 and the five high-order bits in RP1 (10101B) become the five high-order bits of the register address. The three low-order bits of the register address (011) are provided by the three low-order bits of the 8-bit instruction address. The five address bits from RP1 and the three address bits from the instruction are concatenated to form the complete register address, 0ABH (10101011B).

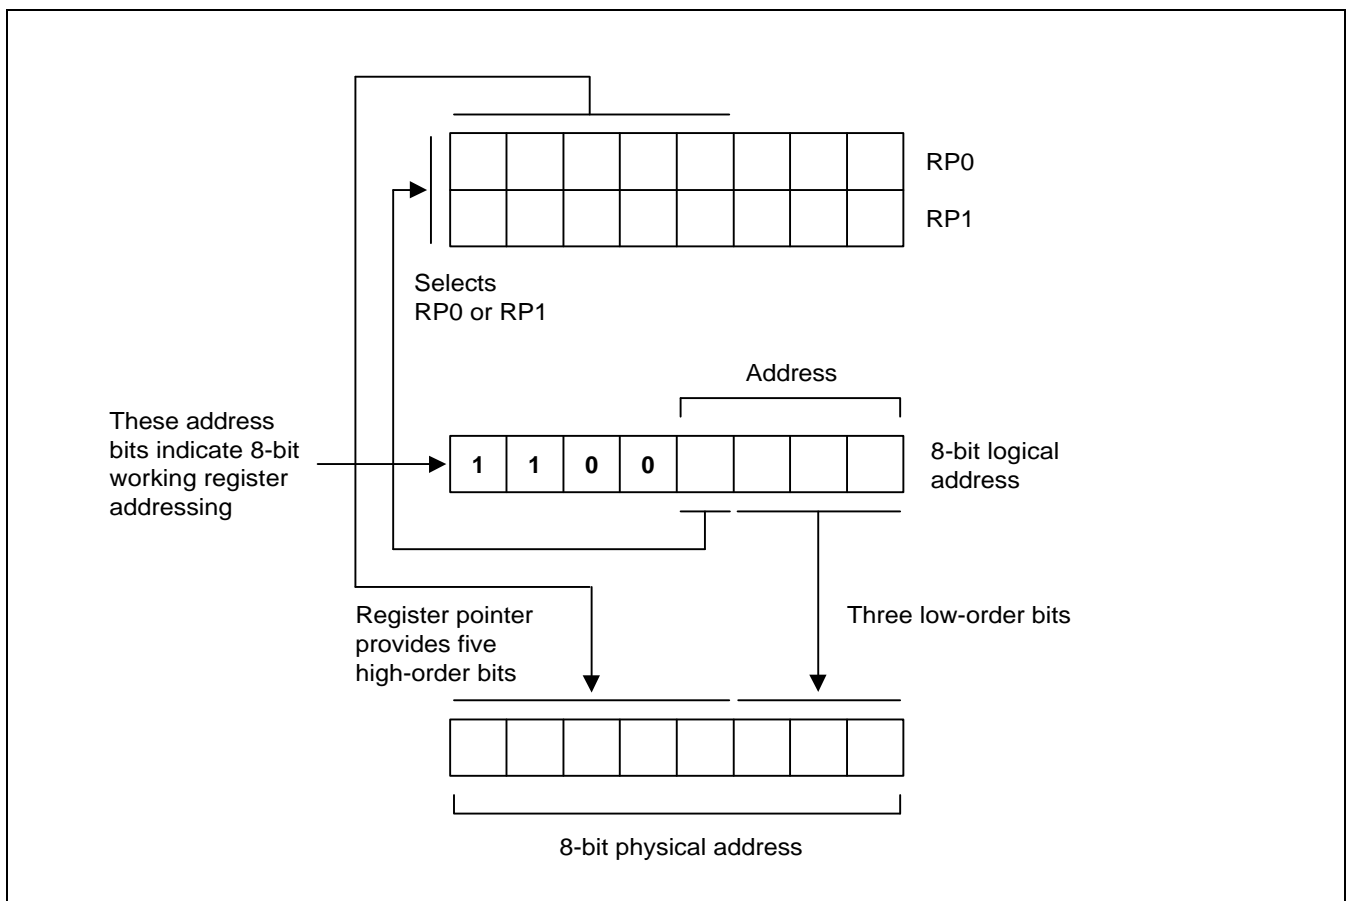

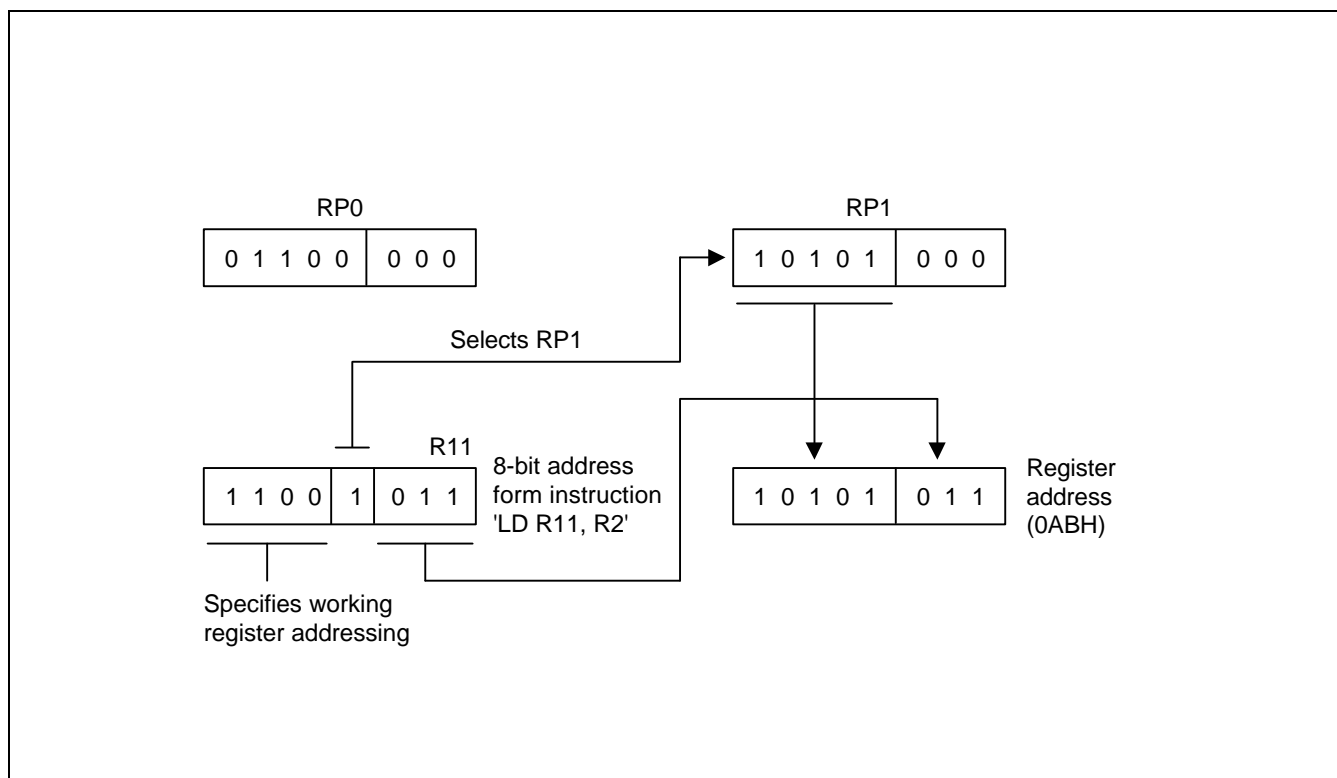

Figure 2-13. 8-Bit Working Register Addressing

**Figure 2-14. 8-Bit Working Register Addressing Example**

SYSTEM AND USER STACK

The S3C8-series microcontrollers use the system stack for data storage, subroutine calls and returns. The PUSH and POP instructions are used to control system stack operations. The S3C831B architecture supports stack operations in the internal register file.

Stack Operations

Return addresses for procedure calls, interrupts, and data are stored on the stack. The contents of the PC are saved to stack by a CALL instruction and restored by the RET instruction. When an interrupt occurs, the contents of the PC and the FLAGS register are pushed to the stack. The IRET instruction then pops these values back to their original locations. The stack address value is always decreased by one before a push operation and increased by one *after* a pop operation. The stack pointer (SP) always points to the stack frame stored on the top of the stack, as shown in Figure 2-15.

Figure 2-15. Stack Operations

User-Defined Stacks

You can freely define stacks in the internal register file as data storage locations. The instructions PUSHUI, PUSHUD, POPUI, and POPUD support user-defined stack operations.

Stack Pointers (SPL, SPH)

Register locations D8H and D9H contain the 16-bit stack pointer (SP) that is used for system stack operations. The most significant byte of the SP address, SP15–SP8, is stored in the SPH register (D8H), and the least significant byte, SP7–SP0, is stored in the SPL register (D9H). After a reset, the SP value is undetermined.

Because only internal memory space is implemented in the S3C831B, the SPL must be initialized to an 8-bit value in the range 00H–FFH. The SPH register is not needed and can be used as a general-purpose register, if necessary.

When the SPL register contains the only stack pointer value (that is, when it points to a system stack in the register file), you can use the SPH register as a general-purpose data register. However, if an overflow or underflow condition occurs as a result of increasing or decreasing the stack address value in the SPL register during normal stack operations, the value in the SPL register will overflow (or underflow) to the SPH register, overwriting any other data that is currently stored there. To avoid overwriting data in the SPH register, you can initialize the SPL value to "FFH" instead of "00H".

PROGRAMMING TIP — Standard Stack Operations Using PUSH and POP

The following example shows you how to perform stack operations in the internal register file using PUSH and POP instructions:

```

LD      SPL,#0FFH      ; SPL ← FFH
                        ; (Normally, the SPL is set to 0FFH by the initialization
                        ; routine)
.
.
.
PUSH    PP              ; Stack address 0FEH ← PP
PUSH    RP0             ; Stack address 0FDH ← RP0
PUSH    RP1             ; Stack address 0FCH ← RP1
PUSH    R3              ; Stack address 0FBH ← R3
.
.
.
POP     R3              ; R3 ← Stack address 0FBH
POP     RP1             ; RP1 ← Stack address 0FCH
POP     RP0             ; RP0 ← Stack address 0FDH
POP     PP              ; PP ← Stack address 0FEH

```

NOTES

3

ADDRESSING MODES

OVERVIEW

Instructions that are stored in program memory are fetched for execution using the program counter. Instructions indicate the operation to be performed and the data to be operated on. Addressing mode is the method used to determine the location of the data operand. The operands specified in SAM88RC instructions may be condition codes, immediate data, or a location in the register file, program memory, or data memory.

The S3C8-series instruction set supports seven explicit addressing modes. Not all of these addressing modes are available for each instruction. The seven addressing modes and their symbols are:

- Register (R)
- Indirect Register (IR)
- Indexed (X)
- Direct Address (DA)
- Indirect Address (IA)
- Relative Address (RA)
- Immediate (IM)

REGISTER ADDRESSING MODE (R)

In Register addressing mode (R), the operand value is the content of a specified register or register pair (see Figure 3-1).

Working register addressing differs from Register addressing in that it uses a register pointer to specify an 8-byte working register space in the register file and an 8-bit register within that space (see Figure 3-2).

Figure 3-1. Register Addressing

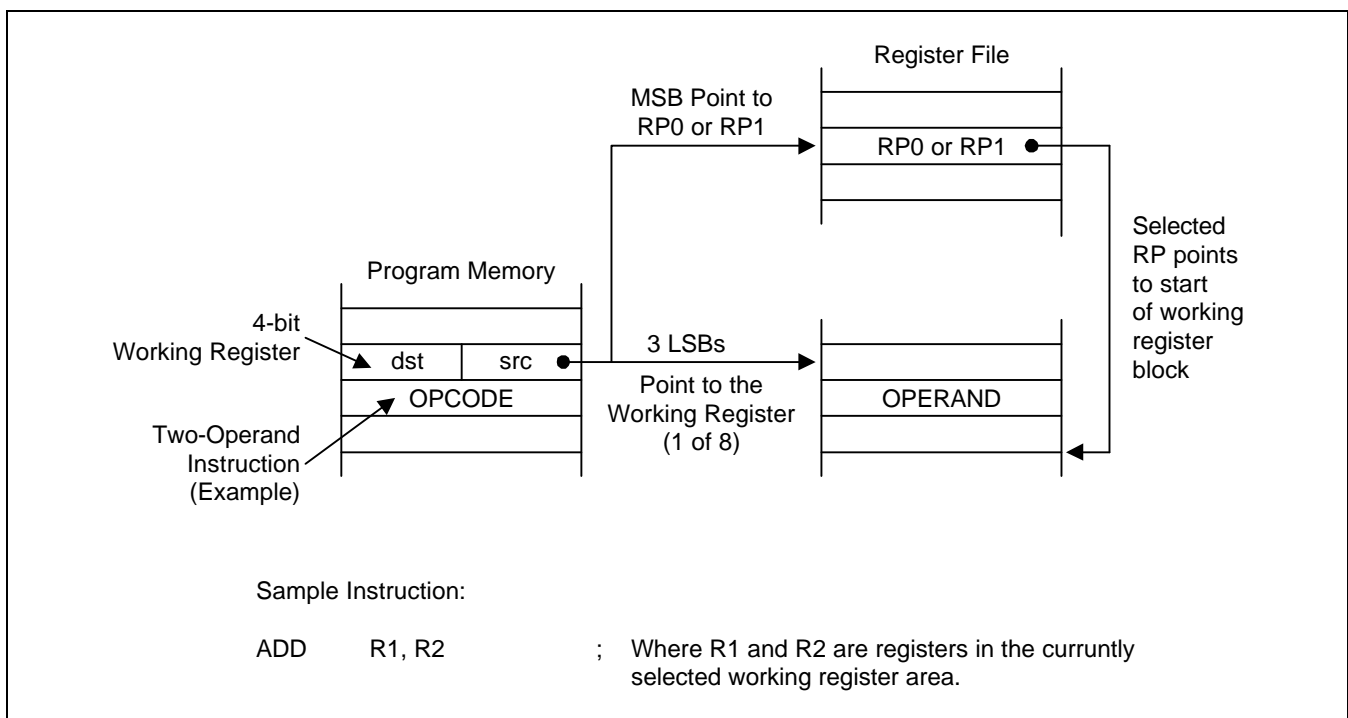

Figure 3-2. Working Register Addressing

INDIRECT REGISTER ADDRESSING MODE (IR)

In Indirect Register (IR) addressing mode, the content of the specified register or register pair is the address of the operand. Depending on the instruction used, the actual address may point to a register in the register file, to program memory (ROM), or to an external memory space (see Figures 3-3 through 3-6).

You can use any 8-bit register to indirectly address another register. Any 16-bit register pair can be used to indirectly address another memory location. Please note, however, that you cannot access locations C0H–FFH in set 1 using the Indirect Register addressing mode.

Figure 3-3. Indirect Register Addressing to Register File

INDIRECT REGISTER ADDRESSING MODE (Continued)

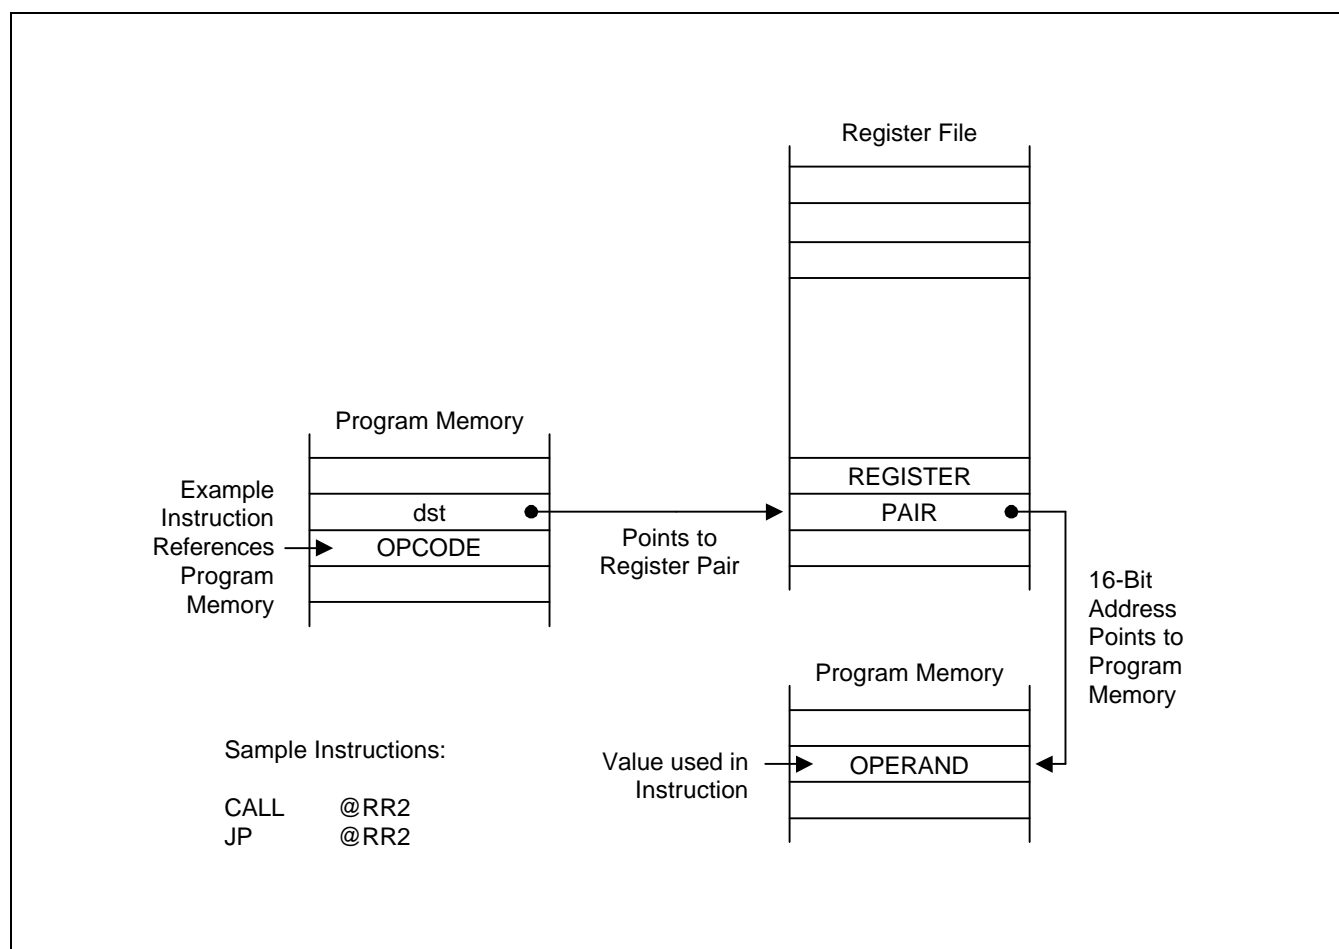

Figure 3-4. Indirect Register Addressing to Program Memory

INDIRECT REGISTER ADDRESSING MODE (Continued)

Figure 3-5. Indirect Working Register Addressing to Register File

INDIRECT REGISTER ADDRESSING MODE (Concluded)

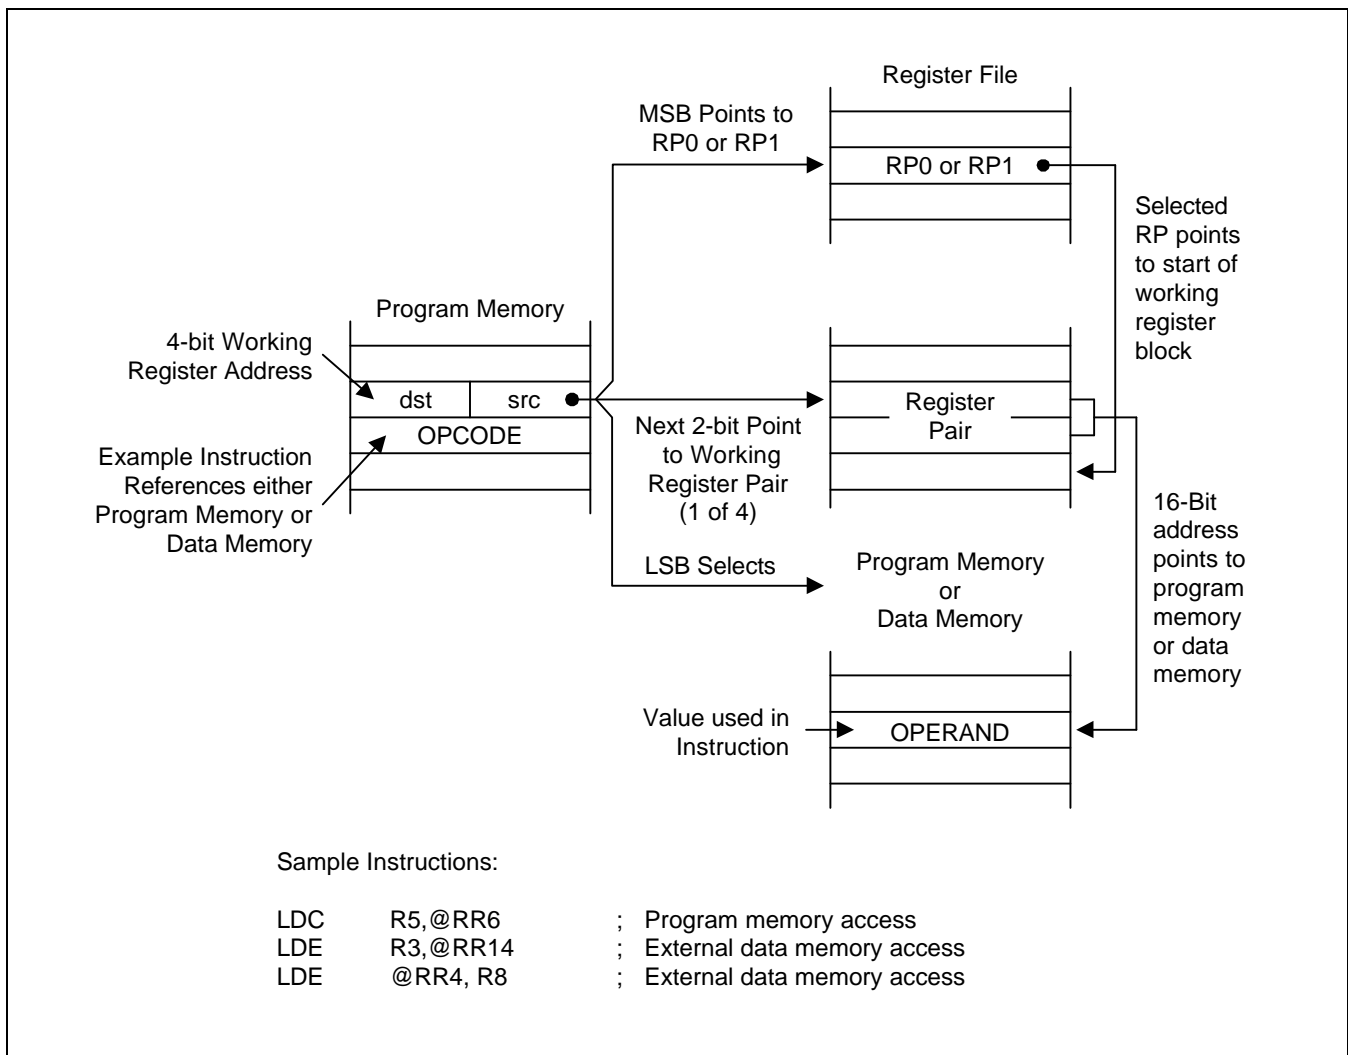

Figure 3-6. Indirect Working Register Addressing to Program or Data Memory

INDEXED ADDRESSING MODE (X)

Indexed (X) addressing mode adds an offset value to a base address during instruction execution in order to calculate the effective operand address (see Figure 3-7). You can use Indexed addressing mode to access locations in the internal register file or in external memory. Please note, however, that you cannot access locations C0H–FFH in set 1 using Indexed addressing mode.

In short offset Indexed addressing mode, the 8-bit displacement is treated as a signed integer in the range –128 to +127. This applies to external memory accesses only (see Figure 3-8.)

For register file addressing, an 8-bit base address provided by the instruction is added to an 8-bit offset contained in a working register. For external memory accesses, the base address is stored in the working register pair designated in the instruction. The 8-bit or 16-bit offset given in the instruction is then added to that base address (see Figure 3-9).

The only instruction that supports Indexed addressing mode for the internal register file is the Load instruction (LD). The LDC and LDE instructions support Indexed addressing mode for internal program memory and for external data memory, when implemented.

Figure 3-7. Indexed Addressing to Register File

INDEXED ADDRESSING MODE (Continued)

Figure 3-8. Indexed Addressing to Program or Data Memory with Short Offset

INDEXED ADDRESSING MODE (Concluded)

Figure 3-9. Indexed Addressing to Program or Data Memory

DIRECT ADDRESS MODE (DA)

In Direct Address (DA) mode, the instruction provides the operand's 16-bit memory address. Jump (JP) and Call (CALL) instructions use this addressing mode to specify the 16-bit destination address that is loaded into the PC whenever a JP or CALL instruction is executed.

The LDC and LDE instructions can use Direct Address mode to specify the source or destination address for Load operations to program memory (LDC) or to external data memory (LDE), if implemented.

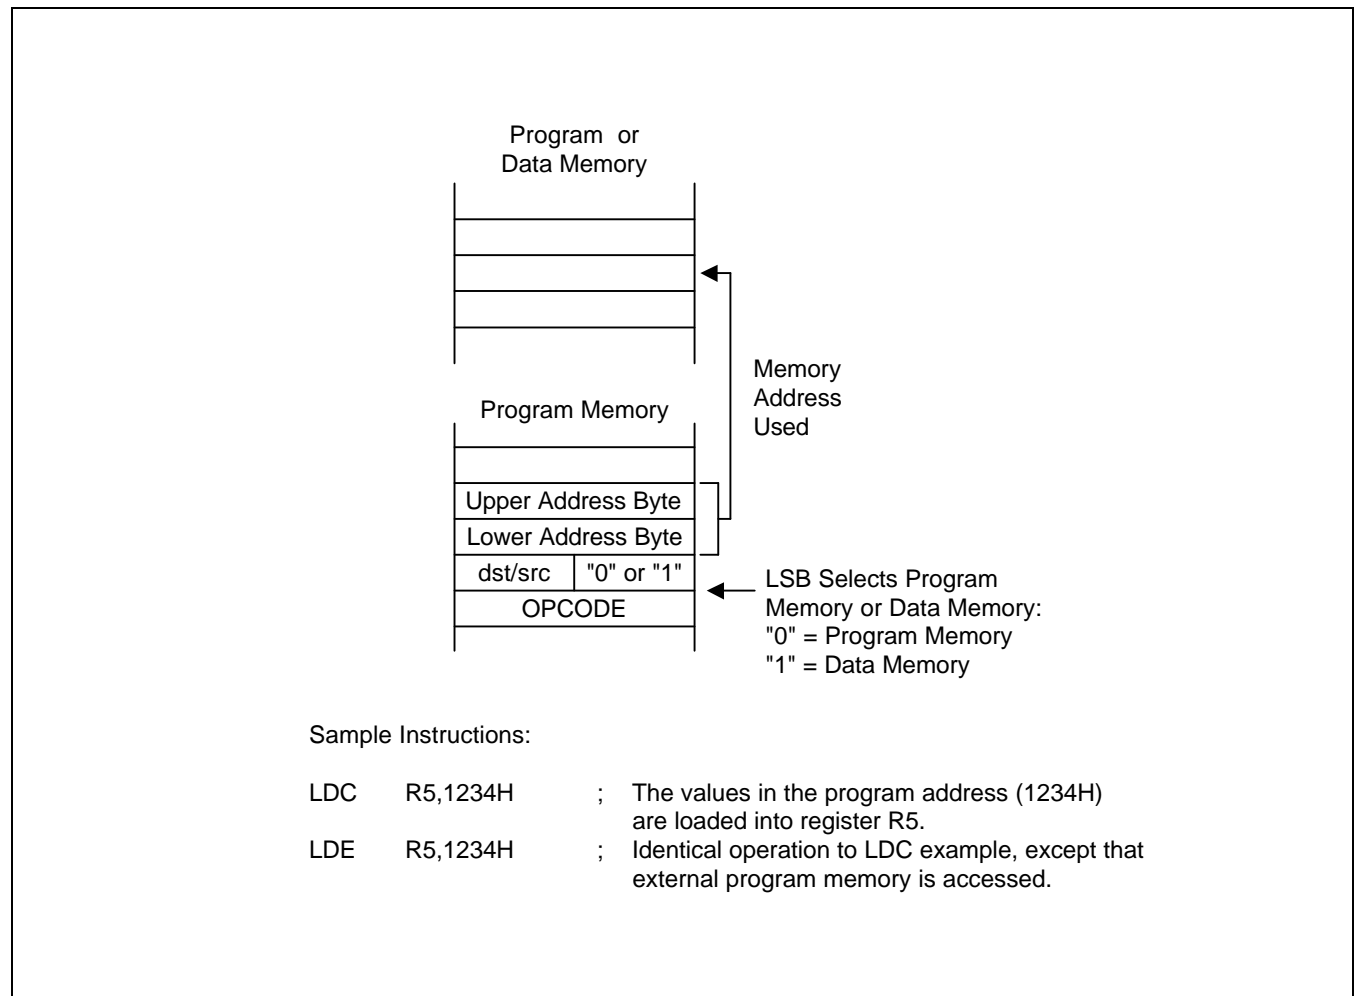

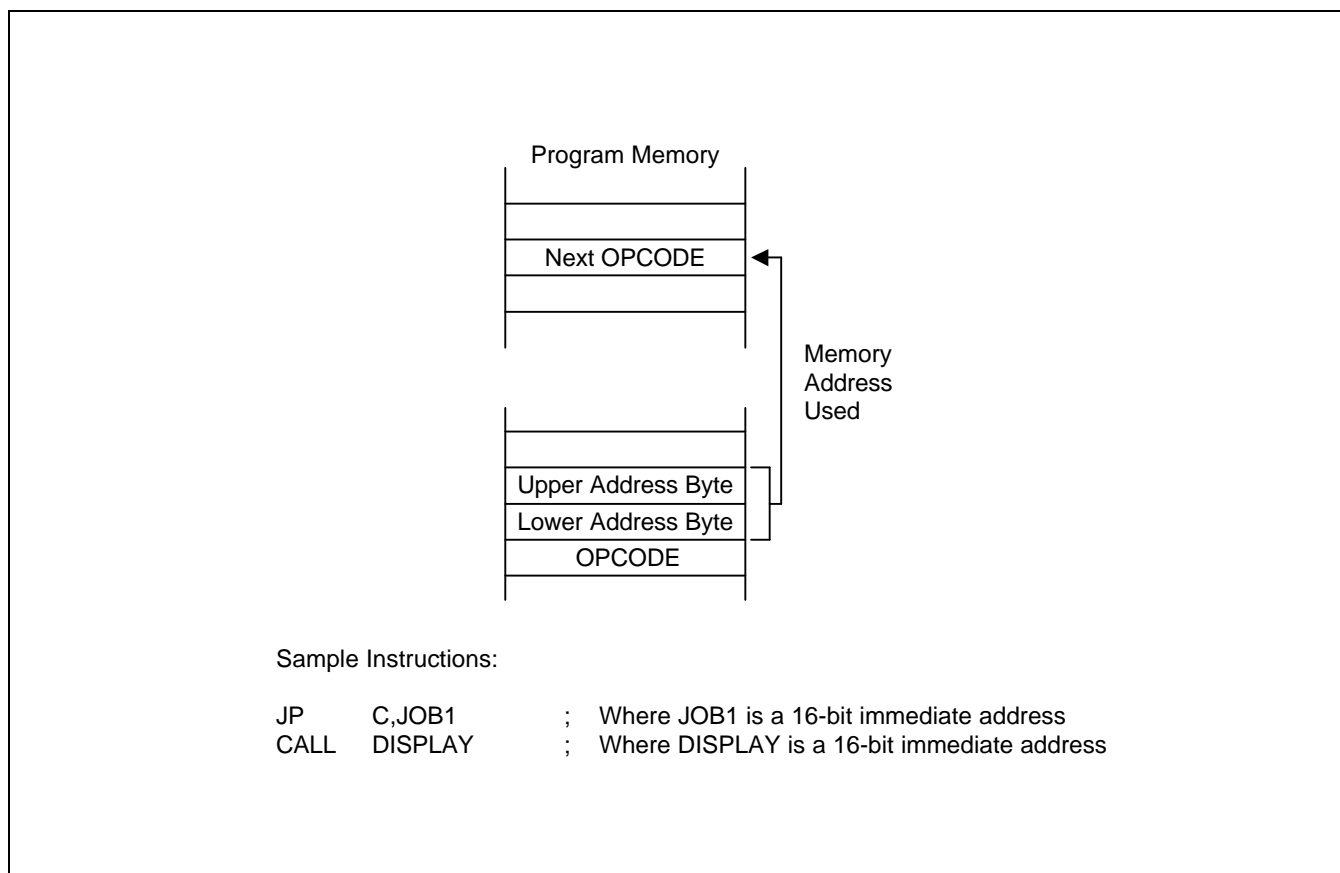

Figure 3-10. Direct Addressing for Load Instructions

DIRECT ADDRESS MODE (Continued)**Figure 3-11. Direct Addressing for Call and Jump Instructions**

INDIRECT ADDRESS MODE (IA)

In Indirect Address (IA) mode, the instruction specifies an address located in the lowest 256 bytes of the program memory. The selected pair of memory locations contains the actual address of the next instruction to be executed. Only the CALL instruction can use the Indirect Address mode.

Because the Indirect Address mode assumes that the operand is located in the lowest 256 bytes of program memory, only an 8-bit address is supplied in the instruction; the upper bytes of the destination address are assumed to be all zeros.

Figure 3-12. Indirect Addressing

RELATIVE ADDRESS MODE (RA)

In Relative Address (RA) mode, a two's-complement signed displacement between -128 and $+127$ is specified in the instruction. The displacement value is then added to the current PC value. The result is the address of the next instruction to be executed. Before this addition occurs, the PC contains the address of the instruction immediately following the current instruction.

Several program control instructions use the Relative Address mode to perform conditional jumps. The instructions that support RA addressing are BTJRF, BTJRT, DJNZ, CPIJE, CPIJNE, and JR.

Figure 3-13. Relative Addressing

IMMEDIATE MODE (IM)

In Immediate (IM) addressing mode, the operand value used in the instruction is the value supplied in the operand field itself. The operand may be one byte or one word in length, depending on the instruction used. Immediate addressing mode is useful for loading constant values into registers.

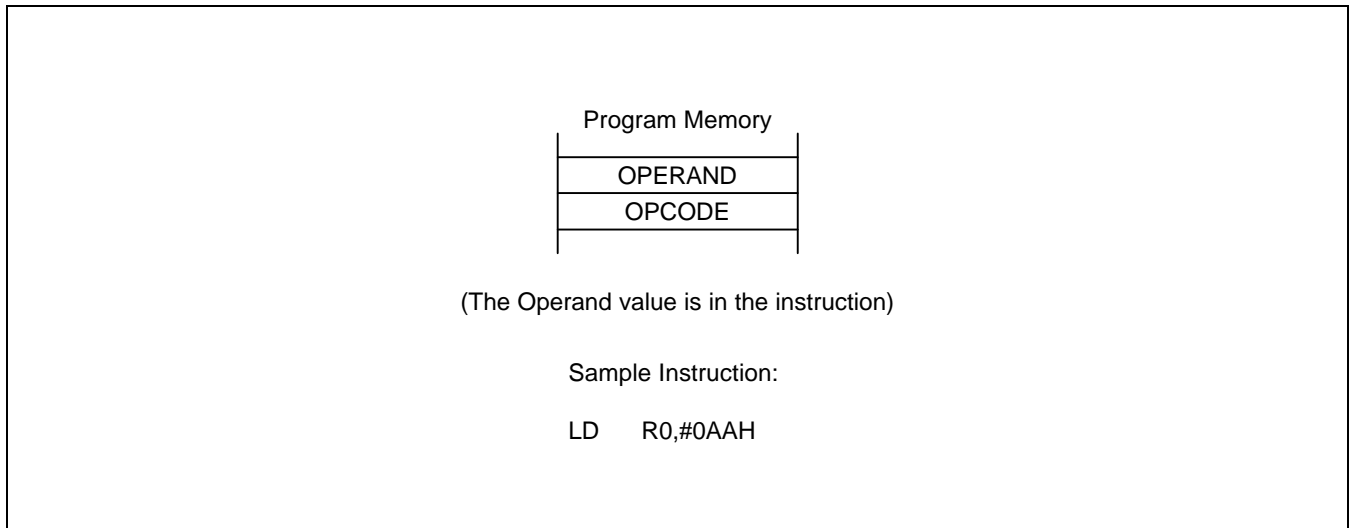

Figure 3-14. Immediate Addressing

CONTROL REGISTERS

OVERVIEW

In this chapter, detailed descriptions of the S3C831B control registers are presented in an easy-to-read format. You can use this chapter as a quick-reference source when writing application programs. Figure 4-1 illustrates the important features of the standard register description format.

Control register descriptions are arranged in alphabetical order according to register mnemonic. More detailed information about control registers is presented in the context of the specific peripheral hardware descriptions in Part II of this manual.

Data and counter registers are not described in detail in this reference chapter. More information about all of the registers used by a specific peripheral is presented in the corresponding peripheral descriptions in Part II of this manual.

The locations and read/write characteristics of all mapped registers in the S3C831B register file are listed in Table 4-1. The hardware reset value for each mapped register is described in Chapter 8, "RESET and Power-Down."

Table 4-1. Set 1 Registers

Register Name	Mnemonic	Address		R/W	RESET Values (bit)							
		Decimal	Hex		7	6	5	4	3	2	1	0
Locations D0H-D2H are not mapped.												
Basic timer control register	BTCON	211	D3H	R/W	0	0	0	0	0	0	0	0
System clock control register	CLKCON	212	D4H	R/W	0	–	–	0	0	–	–	–
System flags register	FLAGS	213	D5H	R/W	x	x	x	x	x	x	0	0
Register pointer 0	RP0	214	D6H	R/W	1	1	0	0	0	–	–	–
Register pointer 1	RP1	215	D7H	R/W	1	1	0	0	1	–	–	–
Stack pointer (high byte)	SPH	216	D8H	R/W	x	x	x	x	x	x	x	x
Stack pointer (low byte)	SPL	217	D9H	R/W	x	x	x	x	x	x	x	x
Instruction pointer (high byte)	IPH	218	DAH	R/W	x	x	x	x	x	x	x	x

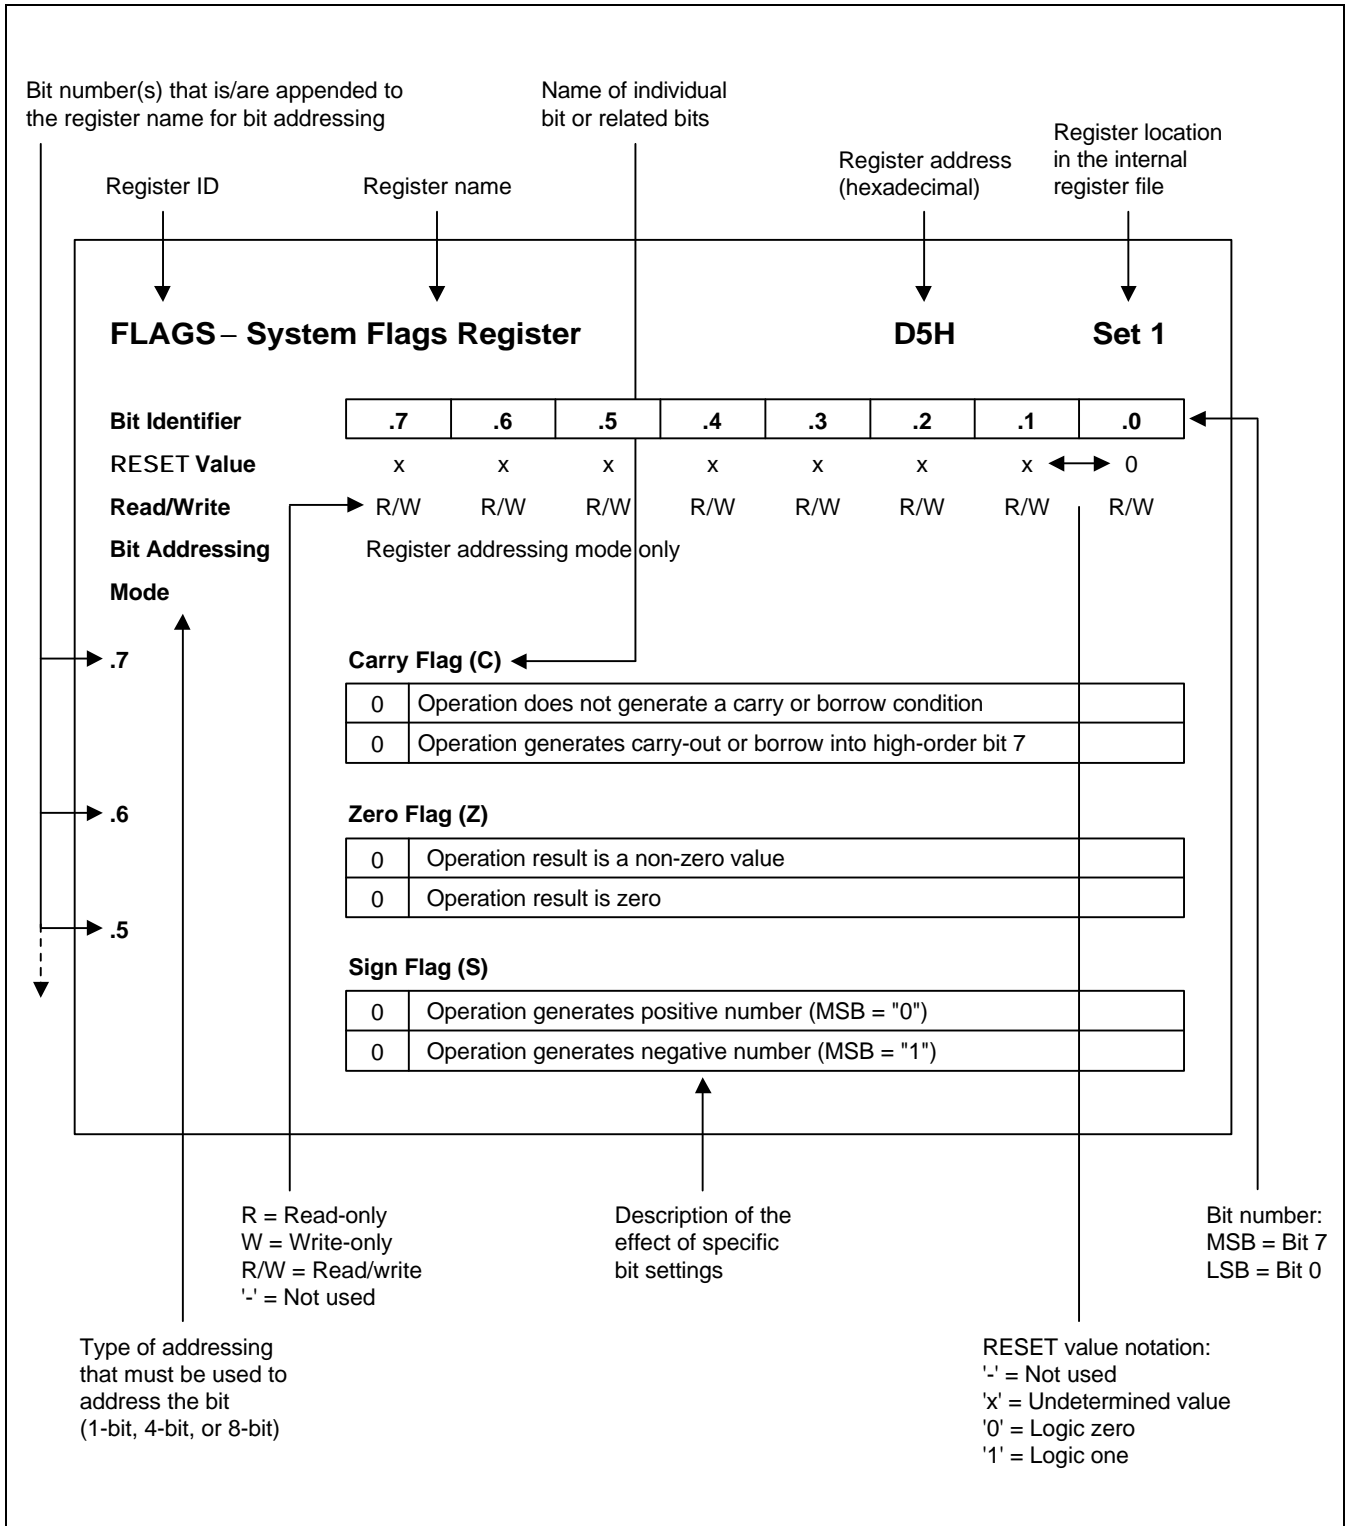

Figure 4-1. Register Description Format

ADCON — A/D Converter Control Register**EFH****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	0	0	0	0	0	0	0
Read/Write	–	R/W	R/W	R/W	R	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7	Not used for the S3C831B
-----------	--------------------------

.6—.4

A/D Input Pin Selection Bits			
0	0	0	AD0 (P2.0)
0	0	1	AD1 (P2.1)
0	1	0	AD2 (P2.2)
0	1	1	AD3 (P2.3)
1	0	0	AD4 (P2.4)
1	0	1	AD5 (P2.5)
1	1	0	AD6 (P2.6)
1	1	1	AD7 (P2.7)

.3	End-of-Conversion Bit (read-only)
0	Conversion not complete
1	Conversion complete

.2—.1

Clock Source Selection Bits		
0	0	fxx/16
0	1	fxx/8
1	0	fxx/4
1	1	fxx

.0	Start or Enable Bit
0	Disable operation
1	Start operation (automatically disable operation after conversion complete).

BTCON — Basic Timer Control Register**D3H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.4**Watchdog Timer Function Disable Code (for System Reset)**

1	0	1	0	Disable watchdog timer function
Others				Enable watchdog timer function

.3–.2**Basic Timer Input Clock Selection Bits**

0	0	fxx/4096 ⁽³⁾
0	1	fxx/1024
1	0	fxx/128
1	1	fxx/16

.1**Basic Timer Counter Clear Bit ⁽¹⁾**

0	No effect
1	Clear the basic timer counter value

.0**Clock Frequency Divider Clear Bit for all timers ⁽²⁾**

0	No effect
1	Clear both clock frequency dividers

NOTES:

- When you write a "1" to BTCON.1, the basic timer counter value is cleared to "00H". Immediately following the write operation, the BTCON.1 value is automatically cleared to "0".
- When you write a "1" to BTCON.0, the corresponding frequency divider is cleared to "00H". Immediately following the write operation, the BTCON.0 value is automatically cleared to "0".
- The fxx is selected clock for system (main OSC. only for S3C831B).

CLKCON — System Clock Control Register**D4H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	—	—	0	0	—	—	—
Read/Write	R/W	—	—	R/W	R/W	—	—	—
Addressing Mode	Register addressing mode only							

.7 Oscillator IRQ Wake-up Function Bit

0	Enable IRQ for main wake-up in power down mode
1	Disable IRQ for main wake-up in power down mode

.6–.5 Not used for the S3C831B**.4–.3 CPU Clock (System Clock) Selection Bits (note)**

0	0	fxx/16
0	1	fxx/8
1	0	fxx/2
1	1	fxx

.2–.0 Not used for the S3C831B

NOTE: After a reset, the slowest clock (divided by 16) is selected as the system clock. To select faster clock speeds, load the appropriate values to CLKCON.3 and CLKCON.4.

FLAGS — System Flags Register**D5H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R	R/W
Addressing Mode	Register addressing mode only							

.7**Carry Flag (C)**

0	Operation does not generate a carry or borrow condition
1	Operation generates a carry-out or borrow into high-order bit 7

.6**Zero Flag (Z)**

0	Operation result is a non-zero value
1	Operation result is zero

.5**Sign Flag (S)**

0	Operation generates a positive number (MSB = "0")
1	Operation generates a negative number (MSB = "1")

.4**Overflow Flag (V)**

0	Operation result is $\leq +127$ or ≥ -128
1	Operation result is $> +127$ or < -128

.3**Decimal Adjust Flag (D)**

0	Add operation completed
1	Subtraction operation completed

.2**Half-Carry Flag (H)**

0	No carry-out of bit 3 or no borrow into bit 3 by addition or subtraction
1	Addition generated carry-out of bit 3 or subtraction generated borrow into bit 3

.1**Fast Interrupt Status Flag (FIS)**

0	Interrupt return (IRET) in progress (when read)
1	Fast interrupt service routine in progress (when read)

.0**Bank Address Selection Flag (BA)**

0	Bank 0 is selected
1	Bank 1 is selected

IFMOD — IF Counter Mode Register**F3H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	–	–	0	0	0	0	0
Read/Write	R/W	–	–	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 System Clock Control Bit for PLL Frequency Synthesizer, IF Counter, Watch Timer

0	The supplied clocks are not divided
1	The supplied clocks are divided by 2.

.6–.5 Not used for the S3C831B**.4 Select the PLL/IFC Operation Voltage**

0	Select the PLL/IFC operation voltage as 4.5V to 5.5V.
1	Select the PLL/IFC operation voltage as 2.5V to 3.5V.

.3–.2 Interrupt Sampling Clock Selection Bits

0	0	IFC is disabled; FMIF/AMIF are pulled down and FMIF/AMIF's feed-back resistor are off.
0	1	Enable IFC operation; AMIF pin is selected; FMIF is pulled down and FMIF's feed-back resistor is off.
1	0	Enable IFC operation; FMIF pin is selected; AMIF is pulled down and AMIF's feed-back resistor is off.
1	1	Enable IFC operation; Both AMIF and FMIF are selected.

.1–.0 Gate Time Selection Bits (fxx = 4.5 MHz) (note)

0	0	Gate opens in 2-millisecond intervals
0	1	Gate opens in 8-millisecond intervals
1	0	Gate opens in 16-millisecond intervals
1	1	Gate remains open continuously

NOTE: If the main clock is 9MHz, IFMOD.7 should be set to "1".

IMR — Interrupt Mask Register**DDH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 Interrupt Level 7 (IRQ7) Enable Bit; IF Interrupt

0	Disable (mask)
1	Enable (unmask)

.6 Interrupt Level 6 (IRQ6) Enable Bit; CE Interrupt

0	Disable (mask)
1	Enable (unmask)

.5 Interrupt Level 5 (IRQ5) Enable Bit; P1.4-P1.7

0	Disable (mask)
1	Enable (unmask)

.4 Interrupt Level 4 (IRQ4) Enable Bit; P1.0-P1.3

0	Disable (mask)
1	Enable (unmask)

.3 Interrupt Level 3 (IRQ3) Enable Bit; Watch Timer

0	Disable (mask)
1	Enable (unmask)

.2 Interrupt Level 2 (IRQ2) Enable Bit; SIO 0, SIO 1 Interrupt

0	Disable (mask)
1	Enable (unmask)

.1 Interrupt Level 1 (IRQ1) Enable Bit; Timer 1, Timer 2 Interrupt

0	Disable (mask)
1	Enable (unmask)

.0 Interrupt Level 0 (IRQ0) Enable Bit; Timer 0 Match/Capture or Overflow

0	Disable (mask)
1	Enable (unmask)

NOTE: When an interrupt level is masked, any interrupt requests that may be issued are not recognized by the CPU.

INTPND — Interrupt Pending Register**E6H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	—	—	—	—	—	—	0	0
Read/Write	—	—	—	—	—	—	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.2

Not used for the S3C831B

.1**Timer 0 Match/Capture Interrupt Pending Bit**

0	Interrupt request is not pending (when read), pending bit clear (when write 0)
1	Interrupt request is pending

.0**Timer 0 Overflow Interrupt Pending Bit**

0	Interrupt request is not pending (when read), pending bit clear (when write 0)
1	Interrupt request is pending

IPH — Instruction Pointer (High Byte)**DAH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0**Instruction Pointer Address (High Byte)**

The high-byte instruction pointer value is the upper eight bits of the 16-bit instruction pointer address (IP15–IP8). The lower byte of the IP address is located in the IPL register (DBH).

IPL — Instruction Pointer (Low Byte)**DBH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0**Instruction Pointer Address (Low Byte)**

The low-byte instruction pointer value is the lower eight bits of the 16-bit instruction pointer address (IP7–IP0). The upper byte of the IP address is located in the IPH register (DAH).

IPR — Interrupt Priority Register**FFH****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7, .4, and .1**Priority Control Bits for Interrupt Groups A, B, and C (note)**

0	0	0	Group priority undefined
0	0	1	B > C > A
0	1	0	A > B > C
0	1	1	B > A > C
1	0	0	C > A > B
1	0	1	C > B > A
1	1	0	A > C > B
1	1	1	Group priority undefined

.6**Interrupt Subgroup C Priority Control Bit**

0	IRQ6 > IRQ7
1	IRQ7 > IRQ6

.5**Interrupt Group C Priority Control Bit**

0	IRQ5 > (IRQ6, IRQ7)
1	(IRQ6, IRQ7) > IRQ5

.3**Interrupt Subgroup B Priority Control Bit**

0	IRQ3 > IRQ4
1	IRQ4 > IRQ3

.2**Interrupt Group B Priority Control Bit**

0	IRQ2 > (IRQ3, IRQ4)
1	(IRQ3, IRQ4) > IRQ2

.0**Interrupt Group A Priority Control Bit**

0	IRQ0 > IRQ1
1	IRQ1 > IRQ0

NOTE: Interrupt Group A - IRQ0, IRQ1
 Interrupt Group B - IRQ2, IRQ3, IRQ4
 Interrupt Group C - IRQ5, IRQ6, IRQ7

IRQ — Interrupt Request Register**DCH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R	R	R	R	R	R	R	R
Addressing Mode	Register addressing mode only							

.7 Level 7 (IRQ7) Request Pending Bit; IF Interrupt

0	Not pending
1	Pending

.6 Level 6 (IRQ6) Request Pending Bit; CE Interrupt

0	Not pending
1	Pending

.5 Level 5 (IRQ5) Request Pending Bit; P1.4-P1.7

0	Not pending
1	Pending

.4 Level 4 (IRQ4) Request Pending Bit; P1.0-P1.3

0	Not pending
1	Pending

.3 Level 3 (IRQ3) Request Pending Bit; Watch Timer

0	Not pending
1	Pending

.2 Level 2 (IRQ2) Request Pending Bit; SIO 0, SIO 1 Interrupt

0	Not pending
1	Pending

.1 Level 1 (IRQ1) Request Pending Bit; Timer 1, Timer 2 Interrupt

0	Not pending
1	Pending

.0 Level 0 (IRQ0) Request Pending Bit; Timer 0 Match/Capture or Overflow

0	Not pending
1	Pending

LCON — LCD Control Register**F1H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	—	—	—	0	0	0	0
Read/Write	R/W	—	—	—	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7**LCD Output Control Bit**

0	LCD output is low and current to dividing resistors is cut off
1	IF LMOD.3 = "0", LCD display is turned off IF LMOD.3 = "1", output COM and SEG signals in display mode

.6–.4

Not used for the S3C831B.

.3–.0**LCD Port Selection Bit**

0	0	0	0	Select LCD SEG0-39
0	0	0	1	Select LCD SEG0-35/P4.0-4.3 as I/O port
0	0	1	0	Select LCD SEG0-31/P4 as I/O port
0	0	1	1	Select LCD SEG0-27/P4, P5.0-5.3 as I/O port
0	1	0	0	Select LCD SEG0-23/P4, P5 as I/O port
0	1	0	1	Select LCD SEG0-19/P4, P5, P6.0-6.3 as I/O port
0	1	1	0	Select LCD SEG0-15/P4, P5, P6 as I/O port
0	1	1	1	Select LCD SEG0-11/P4, P5, P6, P7.0-7.3 as I/O port
1	0	0	0	Select LCD SEG0-7/P4, P5, P6, P7 as I/O port
1	0	0	1	Select LCD SEG0-3/P4, P5, P6, P7, P8.0-8.3 as I/O port
1	0	1	0	All I/O port (P4-P8)

LMOD — LCD Mode Control Register**F2H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 COM Signal Enable/Disable Bit

0	Enable COM signal
1	Disable COM signal

.6 LCD Voltage Dividing Resistor Control Bit

0	Internal voltage dividing resistors
1	External voltage dividing resistors; internal voltage dividing resistors are off

.5—.4 LCD Clock (LCDCK) Frequency Selection Bits (When fxx = 4.5MHz)

0	0	62.5 Hz at fxx = 4.5 MHz
0	1	125 Hz at fxx = 4.5 MHz
1	0	250 Hz at fxx = 4.5 MHz
1	1	500 Hz at fxx = 4.5 MHz

NOTE: If the main clock is 9MHz, IFMOD.7 should be set to "1".**.3—.0 Duty and Bias Selection for LCD Display**

0	x	x	x	LCD display off (COM and SEG output low)
1	0	0	0	1/4 duty, 1/3 bias
1	0	0	1	1/3 duty, 1/3 bias
1	0	1	1	1/3 duty, 1/2 bias
1	0	1	0	1/2 duty, 1/2 bias
1	1	0	0	Static

P0CONH — Port 0 Control Register (High Byte)**E0H****Set 1, Bank 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6**P0.7/T2OUT**

0	0	Input mode
0	1	Output mode, open-drain
1	0	Alternative function (T2OUT)
1	1	Output mode, push-pull

.5–.4**P0.6/T2CLK**

0	0	Input mode (T2CLK)
0	1	Output mode, open-drain
1	0	Not available
1	1	Output mode, push-pull

.3–.2**P0.5/T1OUT**

0	0	Input mode
0	1	Output mode, open-drain
1	0	Alternative function (T1OUT)
1	1	Output mode, push-pull

.1–.0**P0.4/T1CLK**

0	0	Input mode (T1CLK)
0	1	Output mode, open-drain
1	0	Not available
1	1	Output mode, push-pull

P0CONL — Port 0 Control Register (Low Byte)**E1H****Set 1, Bank 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6**P0.3/T0OUT/T0PWM**

0	0	Input mode
0	1	Output mode, open-drain
1	0	Alternative function (T0OUT, T0PWM)
1	1	Output mode, push-pull

.5–.4**P0.2/T0CAP**

0	0	Input mode (T0CAP)
0	1	Output mode, open-drain
1	0	Not available
1	1	Output mode, push-pull

.3–.2**P0.1/T0CLK**

0	0	Input mode (T0CLK)
0	1	Output mode, open-drain
1	0	Not available
1	1	Output mode, push-pull

.1–.0**P0.0**

0	0	Input mode
0	1	Output mode, open-drain
1	0	Not available
1	1	Output mode, push-pull

POPUR — Port 0 Pull-up Control Register**E2H****Set 1, Bank 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.6**P6.0-P6.3/SEG23-20 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

.5–.4**P6.4-P6.7/SEG19-16 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

.3–.2**P7.0-P7.3/SEG15-12 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

.1–.0**P7.4-P7.7/SEG11-8 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

PG2CON — Port Group 2 Control Register**EFH****Set 1, Bank 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7**SIO1 Output Control Bit**

0	SIO1, SCK1 output is selected as push-pull.
1	SIO1, SCK1 output is selected as open-drain.

.6**SIO0 Output Control Bit**

0	SIO0, SCK0 output is selected as push-pull.
1	SIO0, SCK0 output is selected as open-drain.

.5**P1.4-P1.7 Input Enable Bits**

0	Port 1.4-1.7 input enable
1	Port 1.4-1.7 input disable

.4**P1.0-P1.3 Input Enable Bits**

0	Port 1.0-1.3 input enable
1	Port 1.0-1.3 input disable

.3-.2**P8.0-P8.3/SEG7-4 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

.1-.0**P8.4-P8.7/SEG3-0 Mode Selection Bits**

0	0	Schmitt trigger input mode
0	1	Schmitt trigger input mode, pull-up
1	0	Open-drain output mode
1	1	Push-pull output mode

PLLMOD — PLL Mode Register**F8H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	(note)	(note)	(note)	(note)	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 and .4**PLL Frequency Division Method Selection Bits**

0	0	Direct method for VCOAM input (0.5 to 30MHz)
0	1	Enable 3-bit counter for VCOAM input (0.5 to 30MHz)
1	0	Pulse swallow method for VCOAM input (0.5 to 30MHz)
1	1	Pulse swallow method for VCOFM input (30 to 150MHz)

.6**PLL Enable/Disable Bit**

0	Disable PLL
1	Enable PLL

.5**Bit Value to be Loaded into PLLD0 Register**

NF bit is loaded into the LSB of swallow counter	
--	--

.3**INTIF Interrupt Enable Bit**

0	Disable INTIF interrupt
1	Enable INTIF interrupt

.2**INTIF Interrupt Pending Bit**

0	Interrupt is not pending (when read)
0	Clear pending bit (when write)
1	Interrupt is pending (when read)

.1**INTCE Interrupt Enable Bit**

0	Disable INTCE interrupt requests at the CE pin
1	Enable INTCE interrupt requests at the CE pin

.0**INTCE Interrupt Pending Bit**

0	Interrupt is not pending (when read)
0	Clear pending bit (when write)
1	Interrupt is pending (when read)

NOTE: If a system reset occurs during operation mode, the current value contained is retained. If a system reset occurs after power-on, the value is undefined.

PLLREF — PLL Reference Frequency Selection Register F9H Set 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	(1)	(1)	(1)	(2)	(1)	(1)	(1)	(1)
Read/Write	R	R	R	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 PLL Frequency Synthesizer Locked/Unlocked Status Flag

0	PLL is currently in locked state
1	PLL is currently in unlocked state

.6 CE Pin level Status Flag

0	CE pin is currently low level
1	CE pin is currently high level

.5 IF Counter Gate Open/Close Status Flag

0	Gate is currently open
1	Gate is currently close

.4 Power on Flag ⁽³⁾

0	Clear power-on flag bit (when write)
1	Power-on occurred (when read)

.3 – .0 Reference Frequency Selection Bits (When fxx= 4.5MHz) ⁽⁴⁾

0	0	0	0	1-kHz signal
0	0	0	1	3-kHz signal
0	0	1	0	5-kHz signal
0	0	1	1	6.25-kHz signal
0	1	0	0	9-kHz signal
0	1	0	1	10-kHz signal
0	1	1	0	12.5-kHz signal
0	1	1	1	25-kHz signal
1	0	0	0	50-kHz signal
1	0	0	1	100-kHz signal

NOTES:

1. If a system reset occurs during operation mode, the current value contained is retained. If a system reset occurs after power-on, the value is undefined.
2. If a system reset occurs during operation mode, the current value contained is retained. If a system reset occurs after power-on, the value is "1".
3. The POF bit is read initially to check whether or not power has been turned on.
4. If the main clock is 9MHz, IFMOD.7 should be set to "1".

PP — Register Page Pointer**DFH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.4**Destination Register Page Selection Bits**

0	0	0	0	Destination: page 0
0	0	0	1	Destination: page 1
0	0	1	0	Destination: page 2
0	0	1	1	Destination: page 3
0	1	0	0	Destination: page 4
0	1	0	1	Destination: page 5
0	1	1	0	Destination: page 6
0	1	1	1	Destination: page 7
1	0	0	0	Destination: page 8
1	0	0	1	Destination: page 9

.3 – .0**Source Register Page Selection Bits**

0	0	0	0	Source: page 0
0	0	0	1	Source: page 1
0	0	1	0	Source: page 2
0	0	1	1	Source: page 3
0	1	0	0	Source: page 4
0	1	0	1	Source: page 5
0	1	1	0	Source: page 6
0	1	1	1	Source: page 7
1	0	0	0	Source: page 8
1	0	0	1	Source: page 9

NOTE: In the S3C831B microcontroller, the internal register file is configured as ten pages (Pages 0-9). The pages 0-8 are used for general purpose register file, and page 9 is used for LCD data register or general purpose registers.

RP0 — Register Pointer 0**D6H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	0	—	—	—
Read/Write	R/W	R/W	R/W	R/W	R/W	—	—	—
Addressing Mode	Register addressing only							

.7–.3**Register Pointer 0 Address Value**

Register pointer 0 can independently point to one of the 256-byte working register areas in the register file. Using the register pointers RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP0 points to address C0H in register set 1, selecting the 8-byte working register slice C0H–C7H.

.2–.0

Not used for the S3C831B

RP1 — Register Pointer 1**D7H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	1	1	0	0	1	—	—	—
Read/Write	R/W	R/W	R/W	R/W	R/W	—	—	—
Addressing Mode	Register addressing only							

.7 – .3**Register Pointer 1 Address Value**

Register pointer 1 can independently point to one of the 256-byte working register areas in the register file. Using the register pointers RP0 and RP1, you can select two 8-byte register slices at one time as active working register space. After a reset, RP1 points to address C8H in register set 1, selecting the 8-byte working register slice C8H–CFH.

.2 – .0

Not used for the S3C831B

SIO0CON — SIO 0 Control Register**E9H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 SIO 0 Shift Clock Selection Bit

0	Internal clock (P.S clock)
1	External clock (SCK0)

.6 Data Direction Control Bit

0	MSB-first mode
1	LSB-first mode

.5 SIO 0 Mode Selection Bit

0	Receive-only mode
1	Transmit/receive mode

.4 Shift Clock Edge Selection Bit

0	Tx at falling edges, Rx at rising edges
1	Tx at rising edges, Rx at falling edges

.3 SIO 0 Counter Clear and Shift Start Bit

0	No action
1	Clear 3-bit counter and start shifting

.2 SIO 0 Shift Operation Enable Bit

0	Disable shifter and clock counter
1	Enable shifter and clock counter

.1 SIO 0 Interrupt Enable Bit

0	Disable SIO 0 Interrupt
1	Enable SIO 0 Interrupt

.0 SIO 0 Interrupt Pending Bit

0	No interrupt pending
0	Clear pending condition (when write)
1	Interrupt is pending

SIO1CON — SIO 1 Control Register**ECH****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 SIO 1 Shift Clock Selection Bit

0	Internal clock (P.S clock)
1	External clock (SCK1)

.6 Data Direction Control Bit

0	MSB-first mode
1	LSB-first mode

.5 SIO 1 Mode Selection Bit

0	Receive-only mode
1	Transmit/receive mode

.4 Shift Clock Edge Selection Bit

0	Tx at falling edges, Rx at rising edges
1	Tx at rising edges, Rx at falling edges

.3 SIO 1 Counter Clear and Shift Start Bit

0	No action
1	Clear 3-bit counter and start shifting

.2 SIO 1 Shift Operation Enable Bit

0	Disable shifter and clock counter
1	Enable shifter and clock counter

.1 SIO 1 Interrupt Enable Bit

0	Disable SIO 1 Interrupt
1	Enable SIO 1 Interrupt

.0 SIO 1 Interrupt Pending Bit

0	No interrupt pending
0	Clear pending condition (when write)
1	Interrupt is pending

SPH — Stack Pointer (High Byte)**D8H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0**Stack Pointer Address (High Byte)**

The high-byte stack pointer value is the upper eight bits of the 16-bit stack pointer address (SP15–SP8). The lower byte of the stack pointer value is located in register SPL (D9H). The SP value is undefined following a reset.

SPL — Stack Pointer (Low Byte)**D9H****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	x	x	x	x	x	x	x	x
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0**Stack Pointer Address (Low Byte)**

The low-byte stack pointer value is the lower eight bits of the 16-bit stack pointer address (SP7–SP0). The upper byte of the stack pointer value is located in register SPH (D8H). The SP value is undefined following a reset.

STPCON — Stop Control Register

FBHSet 1, Bank 0

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.0	STOP Control Bits							
	1 0 1 0 0 1 0 1				Enable stop instruction			
	Other values				Disable stop instruction			

NOTE: Before execute the STOP instruction, set this STPCON register as “10100101b”. Otherwise the STOP instruction will not execute as well as reset will be generated.

SYM — System Mode Register**DEH****Set 1**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	—	—	x	x	x	0	0
Read/Write	R/W	—	—	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7 Not used, But you must keep "0"

.6–.5 Not used for the S3C831B.

.4–.2 **Fast Interrupt Level Selection Bits ⁽¹⁾**

0	0	0	IRQ0
0	0	1	IRQ1
0	1	0	IRQ2
0	1	1	IRQ3
1	0	0	IRQ4
1	0	1	IRQ5
1	1	0	IRQ6
1	1	1	IRQ7

.1 **Fast Interrupt Enable Bit ⁽²⁾**

0	Disable fast interrupt processing
1	Enable fast interrupt processing

.0 **Global Interrupt Enable Bit ⁽³⁾**

0	Disable all interrupt processing
1	Enable all interrupt processing

NOTES:

1. You can select only one interrupt level at a time for fast interrupt processing.
2. Setting SYM.1 to "1" enables fast interrupt processing for the interrupt level currently selected by SYM.2-SYM.4.
3. Following a reset, you must enable global interrupt processing by executing an EI instruction (not by writing a "1" to SYM.0).

T0CON — Timer 0 Control Register**E2H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.5**Timer 0 Input Clock Selection Bits**

0	0	0	fxx/1024
0	0	1	fxx/256
0	1	0	fxx/64
0	1	1	fxx/8
1	0	0	fxx
1	0	1	External clock (T0CLK) falling edge
1	1	0	External clock (T0CLK) rising edge
1	1	1	Counter stop

.4–.3**Timer 0 Operating Mode Selection Bits**

0	0	Interval mode
0	1	Capture mode (capture on rising edge, counter running, OVF can occur)
1	0	Capture mode (capture on falling edge, counter running, OVF can occur)
1	1	PWM mode (OVF & match interrupt can occur)

.2**Timer 0 Counter Clear Bit (note)**

0	No effect
1	Clear the timer 0 counter (when write)

.1**Timer 0 Match/Capture Interrupt Enable Bit**

0	Disable interrupt
1	Enable interrupt

.0**Timer 0 Overflow Interrupt Enable**

0	Disable overflow interrupt
1	Enable overflow interrupt

NOTE: When you write a "1" to T0CON.2, the timer 0 counter value is cleared to "00H". Immediately following the write operation, the T0CON.2 value is automatically cleared to "0".

T1CON — Timer 1 Control Register**E5H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.5**Timer 1 Input Clock Selection Bits**

0	0	0	fxx/256
0	0	1	fxx/64
0	1	0	fxx/8
0	1	1	fxx
1	1	1	External clock (T1CLK) input

.4

Not used for the S3C831B

.3**Timer 1 Counter Clear Bit** ^(Note)

0	No effect
1	Clear the timer 1 counter (when write)

.2**Timer 1 Counter Enable Bit**

0	Disable counting operation
1	Enable counting operation

.1**Timer 1 Interrupt Enable Bit**

0	Disable timer 1 interrupt
1	Enable timer 1 interrupt

.0**Timer 1 Interrupt Pending Bit**

0	No timer 1 interrupt pending (when read)
0	Clear timer 1 interrupt pending condition (when write)
1	T1 interrupt is pending

NOTE: When you write a "1" to T1CON.3, the timer 1 counter value is cleared to "00H". Immediately following the write operation, the T1CON.3 value is automatically cleared to "0".

T2CON — Timer 2 Control Register

FEH

Set 1, Bank 1

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	0	0	0	0	0	0	0	0
Read/Write	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7–.5**Timer 2 Input Clock Selection Bits**

0	0	0	fxx/256
0	0	1	fxx/64
0	1	0	fxx/8
0	1	1	fxx
1	1	1	External clock (T2CLK) input

.4

Not used for the S3C831B.

.3**Timer 2 Counter Clear Bit** ^(Note)

0	No effect
1	Clear the timer 2 counter (when write)

.2**Timer 2 Counter Enable Bit**

0	Disable counting operation
1	Enable counting operation

.1**Timer 2 Interrupt Enable Bit**

0	Disable timer 2 interrupt
1	Enable timer 2 interrupt

.0**Timer 2 Interrupt Pending Bit**

0	No timer 2 interrupt pending (when read)
0	Clear timer 2 interrupt pending bit (when write)
1	T2 interrupt is pending

NOTE: When you write a "1" to T2CON.3, the timer 2 counter value is cleared to "00H". Immediately following the write operation, the T2CON.3 value is automatically cleared to "0".

WTCON — Watch Timer Control Register**E8H****Set 1, Bank 0**

Bit Identifier	.7	.6	.5	.4	.3	.2	.1	.0
RESET Value	–	0	0	0	0	0	0	0
Read/Write	–	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Addressing Mode	Register addressing mode only							

.7	Not used for the S3C831B.
----	---------------------------

.6	Watch Timer Enable Bit
0	Disable watch timer; clear frequency dividing circuits
1	Enable watch timer

.5–.4

Buzzer Signal Selection Bits (When fxx= 4.5 MHz)		
0	0	1 kHz buzzer (BUZ) signal output
0	1	1.5 kHz buzzer (BUZ) signal output
1	0	3 kHz buzzer (BUZ) signal output
1	1	6 kHz buzzer (BUZ) signal output

.3—.2

Watch Timer Speed Selection Bits (When fxx=4.5 MHz)		
0	0	1.0 s Interval
0	1	0.5 s Interval
1	1	50 ms Interval

.1	Watch Timer Interrupt Enable Bit
0	Disable watch timer interrupt
1	Enable watch timer interrupt

.0	Watch Timer Interrupt Pending Bit
0	Interrupt is not pending (when read)
1	Clear pending bit (when write)
1	Interrupt is pending (when read)

NOTE: If the main clock is 9MHz, IFMOD.7 should be set to "1".

5

INTERRUPT STRUCTURE

OVERVIEW

The S3C8-series interrupt structure has three basic components: levels, vectors, and sources. The SAM88RC CPU recognizes up to eight interrupt levels and supports up to 128 interrupt vectors. When a specific interrupt level has more than one vector address, the vector priorities are established in hardware. A vector address can be assigned to one or more sources.

Levels

Interrupt levels are the main unit for interrupt priority assignment and recognition. All peripherals and I/O blocks can issue interrupt requests. In other words, peripheral and I/O operations are interrupt-driven. There are eight possible interrupt levels: IRQ0–IRQ7, also called level 0–level 7. Each interrupt level directly corresponds to an interrupt request number (IRQn). The total number of interrupt levels used in the interrupt structure varies from device to device. The S3C831B interrupt structure recognizes eight interrupt levels.

The interrupt level numbers 0 through 7 do not necessarily indicate the relative priority of the levels. They are just identifiers for the interrupt levels that are recognized by the CPU. The relative priority of different interrupt levels is determined by settings in the interrupt priority register, IPR. Interrupt group and subgroup logic controlled by IPR settings lets you define more complex priority relationships between different levels.

Vectors

Each interrupt level can have one or more interrupt vectors, or it may have no vector address assigned at all. The maximum number of vectors that can be supported for a given level is 128 (The actual number of vectors used for S3C8-series devices is always much smaller). If an interrupt level has more than one vector address, the vector priorities are set in hardware. S3C831B uses seventeen vectors.

Sources

A source is any peripheral that generates an interrupt. A source can be an external pin or a counter overflow. Each vector can have several interrupt sources. In the S3C831B interrupt structure, there are seventeen possible interrupt sources.

When a service routine starts, the respective pending bit should be either cleared automatically by hardware or cleared "manually" by program software. The characteristics of the source's pending mechanism determine which method would be used to clear its respective pending bit.

INTERRUPT TYPES

The three components of the S3C8 interrupt structure described before — levels, vectors, and sources — are combined to determine the interrupt structure of an individual device and to make full use of its available interrupt logic. There are three possible combinations of interrupt structure components, called interrupt types 1, 2, and 3. The types differ in the number of vectors and interrupt sources assigned to each level (see Figure 5-1):

- Type 1: One level (IRQn) + one vector (V_1) + one source (S_1)
- Type 2: One level (IRQn) + one vector (V_1) + multiple sources ($S_1 - S_n$)
- Type 3: One level (IRQn) + multiple vectors ($V_1 - V_n$) + multiple sources ($S_1 - S_n, S_{n+1} - S_{n+m}$)

In the S3C831B microcontroller, two interrupt types are implemented.

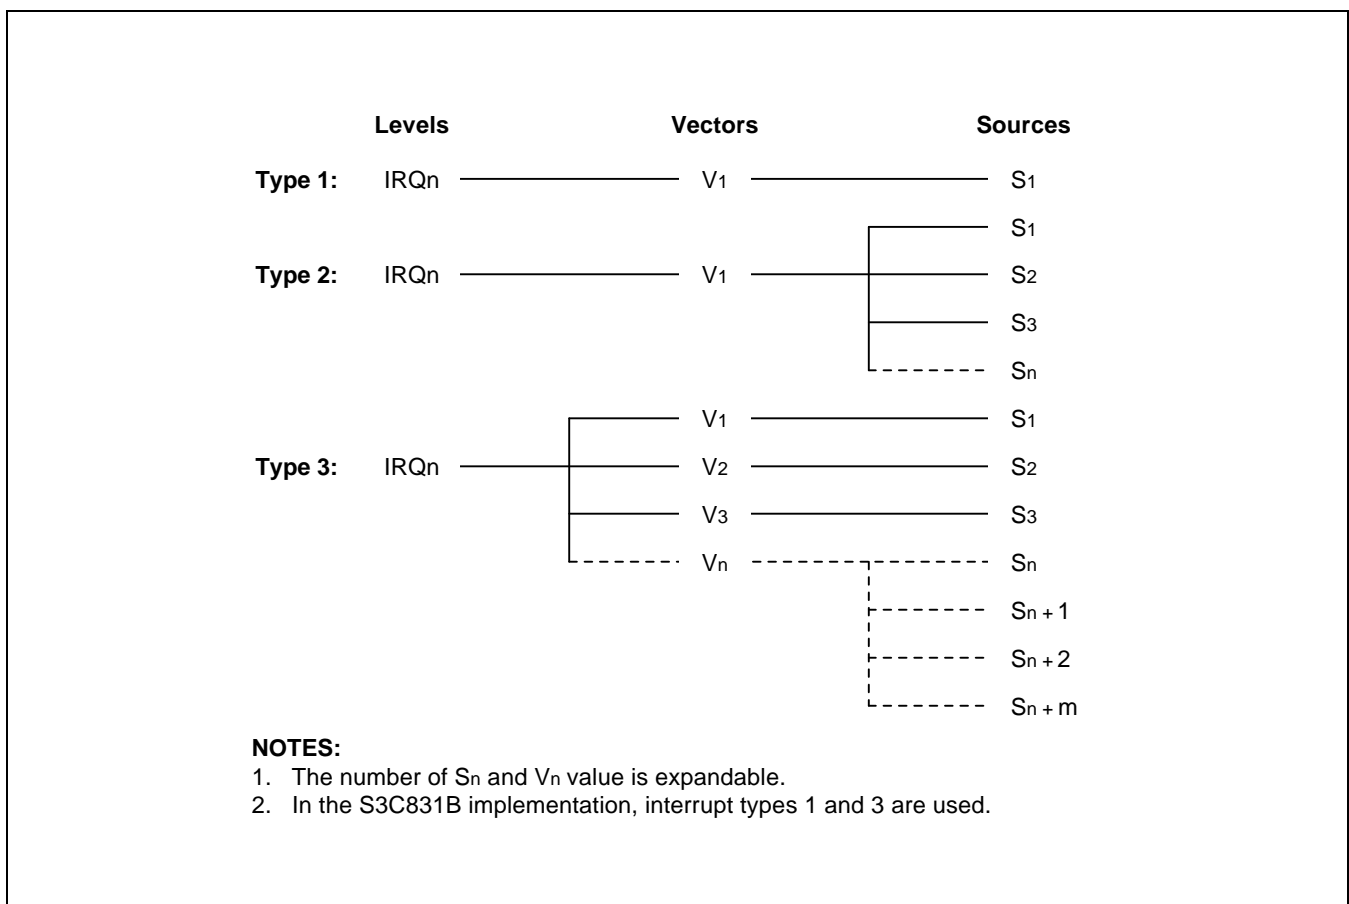

Figure 5-1. S3C8-Series Interrupt Types

S3C831B INTERRUPT STRUCTURE

The S3C831B microcontroller supports seventeen interrupt sources. All seventeen of the interrupt sources have a corresponding interrupt vector address. Eight interrupt levels are recognized by the CPU in this device-specific interrupt structure, as shown in Figure 5-2.

When multiple interrupt levels are active, the interrupt priority register (IPR) determines the order in which contending interrupts are to be serviced. If multiple interrupts occur within the same interrupt level, the interrupt with the lowest vector address is usually processed first (The relative priorities of multiple interrupts within a single level are fixed in hardware).

When the CPU grants an interrupt request, interrupt processing starts. All other interrupts are disabled and the program counter value and status flags are pushed to stack. The starting address of the service routine is fetched from the appropriate vector address (plus the next 8-bit value to concatenate the full 16-bit address) and the service routine is executed.

Levels	Vectors	Sources	Reset/Clear
RESET	100H	Basic timer overflow	H/W
IRQ0	E0H	Timer 0 match/capture	S/W
	E2H	Timer 0 overflow	H/W,S/W
IRQ1	E4H	Timer 2 match	S/W
	E6H	Timer 1 match	S/W
IRQ2	E8H	SIO1 interrupt	S/W
	EAH	SIO0 interrupt	S/W
IRQ3	F2H	Watch timer	S/W
IRQ4	D0H	P1.0 external interrupt	S/W
	D2H	P1.1 external interrupt	S/W
	D4H	P1.2 external interrupt	S/W
	D6H	P1.3 external interrupt	S/W
IRQ5	D8H	P1.4 external interrupt	S/W
	DAH	P1.5 external interrupt	S/W
	DCH	P1.6 external interrupt	S/W
	DEH	P1.7 external interrupt	S/W
IRQ6	C0H	CE interrupt	S/W
IRQ7	C2H	IF interrupt	S/W

NOTES:

1. Within a given interrupt level, the low vector address has high priority.
For example, E0H has higher priority than E2H within the level IRQ0.
The priorities within each level are set at the factory.
2. External interrupts are triggered by a rising or falling edge, depending on the corresponding control register setting.

Figure 5-2. S3C831B Interrupt Structure

INTERRUPT VECTOR ADDRESSES

All interrupt vector addresses for the S3C831B interrupt structure are stored in the vector address area of the first 256 bytes of the program memory (ROM).

You can allocate unused locations in the vector address area as normal program memory. If you do so, please be careful not to overwrite any of the stored vector addresses (Table 5-1 lists all vector addresses).

The program reset address in the ROM is 0100H.

Figure 5-3. ROM Vector Address Area

Table 5-1. Interrupt Vectors

Vector Address		Interrupt Source	Request		Reset/Clear	
Decimal Value	Hex Value		Interrupt Level	Priority in Level	H/W	S/W
256	100H	Basic timer overflow	RESET	–	√	
226	E2H	Timer 0 overflow	IRQ0	1	√	√
224	E0H	Timer 0 match/capture		0		√
230	E6H	Timer 1 match	IRQ1	1		√
228	E4H	Timer 2 match		0		√
234	EAH	SIO0 interrupt	IRQ2	1		√
232	E8H	SIO1 interrupt		0		√
242	F2H	Watch timer	IRQ3	–		√
214	D6H	P1.3 external interrupt	IRQ4	3		√
212	D4H	P1.2 external interrupt		2		√
210	D2H	P1.1 external interrupt		1		√
208	D0H	P1.0 external interrupt		0		√
222	DEH	P1.7 external interrupt	IRQ5	3		√
220	DCH	P1.6 external interrupt		2		√
218	DAH	P1.5 external interrupt		1		√
216	D8H	P1.4 external interrupt		0		√
192	C0H	CE interrupt	IRQ6	–		√
194	C2H	IF interrupt	IRQ7	–		√

NOTES:

1. Interrupt priorities are identified in inverse order: "0" is the highest priority, "1" is the next highest, and so on.
2. If two or more interrupts within the same level contend, the interrupt with the lowest vector address usually has priority over one with a higher vector address. The priorities within a given level are fixed in hardware.

ENABLE/DISABLE INTERRUPT INSTRUCTIONS (EI, DI)

Executing the Enable Interrupts (EI) instruction globally enables the interrupt structure. All interrupts are then serviced as they occur according to the established priorities.

NOTE

The system initialization routine executed after a reset must always contain an EI instruction to globally enable the interrupt structure.

During the normal operation, you can execute the DI (Disable Interrupt) instruction at any time to globally disable interrupt processing. The EI and DI instructions change the value of bit 0 in the SYM register.

SYSTEM-LEVEL INTERRUPT CONTROL REGISTERS

In addition to the control registers for specific interrupt sources, four system-level registers control interrupt processing:

- The interrupt mask register, IMR, enables (un-masks) or disables (masks) interrupt levels.
- The interrupt priority register, IPR, controls the relative priorities of interrupt levels.
- The interrupt request register, IRQ, contains interrupt pending flags for each interrupt level (as opposed to each interrupt source).
- The system mode register, SYM, enables or disables global interrupt processing (SYM settings also enable fast interrupts and control the activity of external interface, if implemented).

Table 5-2. Interrupt Control Register Overview

Control Register	ID	R/W	Function Description
Interrupt mask register	IMR	R/W	Bit settings in the IMR register enable or disable interrupt processing for each of the eight interrupt levels: IRQ0–IRQ7.
Interrupt priority register	IPR	R/W	Controls the relative processing priorities of the interrupt levels. The eight levels of S3C831B are organized into three groups: A, B, and C. Group A is IRQ0 and IRQ1, group B is IRQ2, IRQ3 and IRQ4, and group C is IRQ5, IRQ6, and IRQ7.
Interrupt request register	IRQ	R	This register contains a request pending bit for each interrupt level.
System mode register	SYM	R/W	This register enables/disables fast interrupt processing, and dynamic global interrupt processing.

NOTE: Before IMR register is changed to any value, all interrupts must be disable. Using DI instruction is recommended.

INTERRUPT PROCESSING CONTROL POINTS

Interrupt processing can therefore be controlled in two ways: globally or by specific interrupt level and source. The system-level control points in the interrupt structure are:

- Global interrupt enable and disable (by EI and DI instructions or by direct manipulation of SYM.0)
- Interrupt level enable/disable settings (IMR register)
- Interrupt level priority settings (IPR register)
- Interrupt source enable/disable settings in the corresponding peripheral control registers

NOTE

When writing an application program that handles interrupt processing, be sure to include the necessary register file address (register pointer) information.

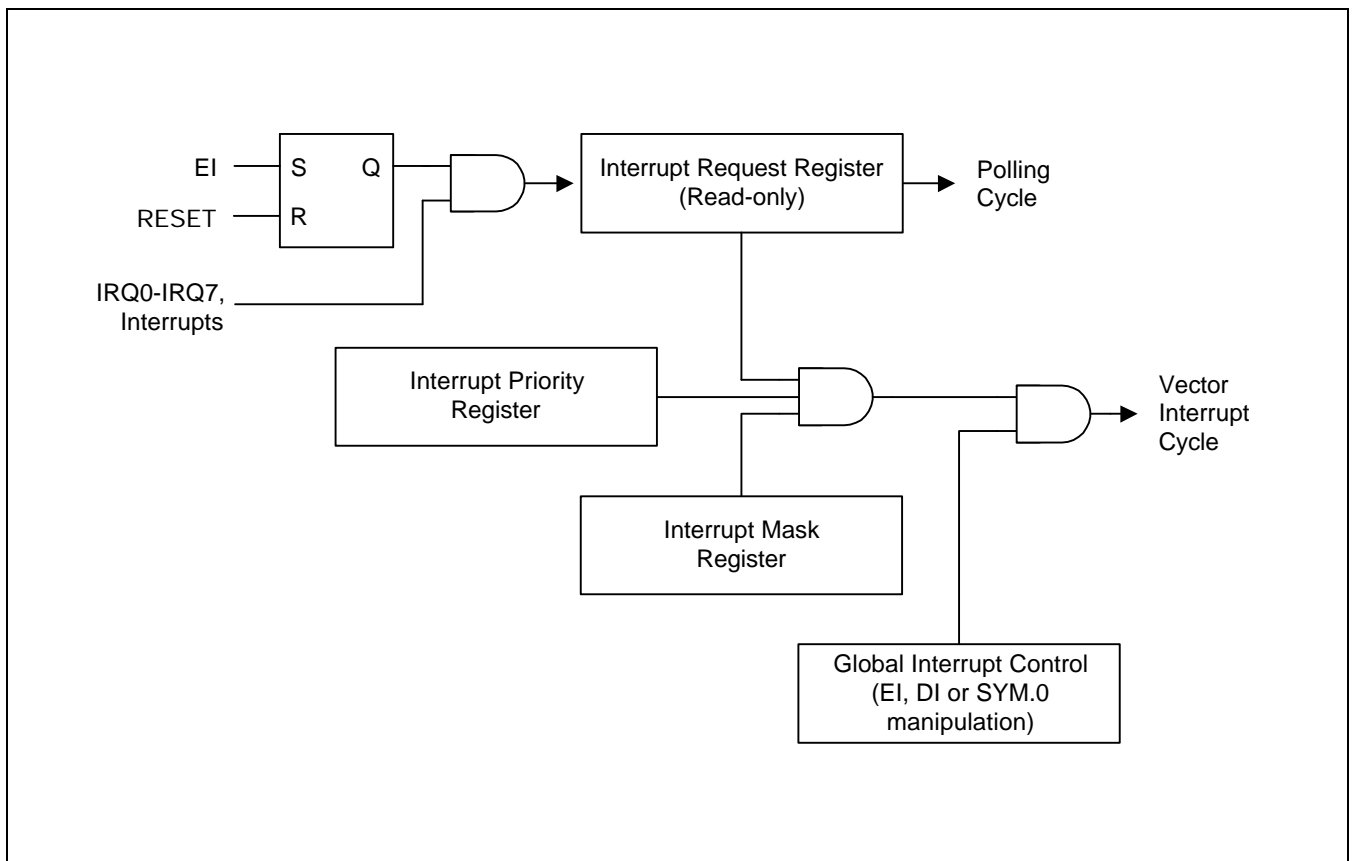

Figure 5-4. Interrupt Function Diagram

PERIPHERAL INTERRUPT CONTROL REGISTERS

For each interrupt source there is one or more corresponding peripheral control registers that let you control the interrupt generated by the related peripheral (see Table 5-3).

Table 5-3. Interrupt Source Control and Data Registers

Interrupt Source	Interrupt Level	Register(s)	Location(s) in Set 1
Timer 0 overflow Timer 0 match/capture	IRQ0	T0CON T0CNT T0DATA INTPND	E2H, bank 0 E0H, bank 0 E1H, bank 0 E6H, bank 0

SYSTEM MODE REGISTER (SYM)

The system mode register, SYM (set 1, DEH), is used to globally enable and disable interrupt processing and to control fast interrupt processing (see Figure 5-5).

A reset clears SYM.1, and SYM.0 to "0". The 3-bit value for fast interrupt level selection, SYM.4–SYM.2, is undetermined.

The instructions EI and DI enable and disable global interrupt processing, respectively, by modifying the bit 0 value of the SYM register. In order to enable interrupt processing an Enable Interrupt (EI) instruction must be included in the initialization routine, which follows a reset operation. Although you can manipulate SYM.0 directly to enable and disable interrupts during the normal operation, it is recommended to use the EI and DI instructions for this purpose.

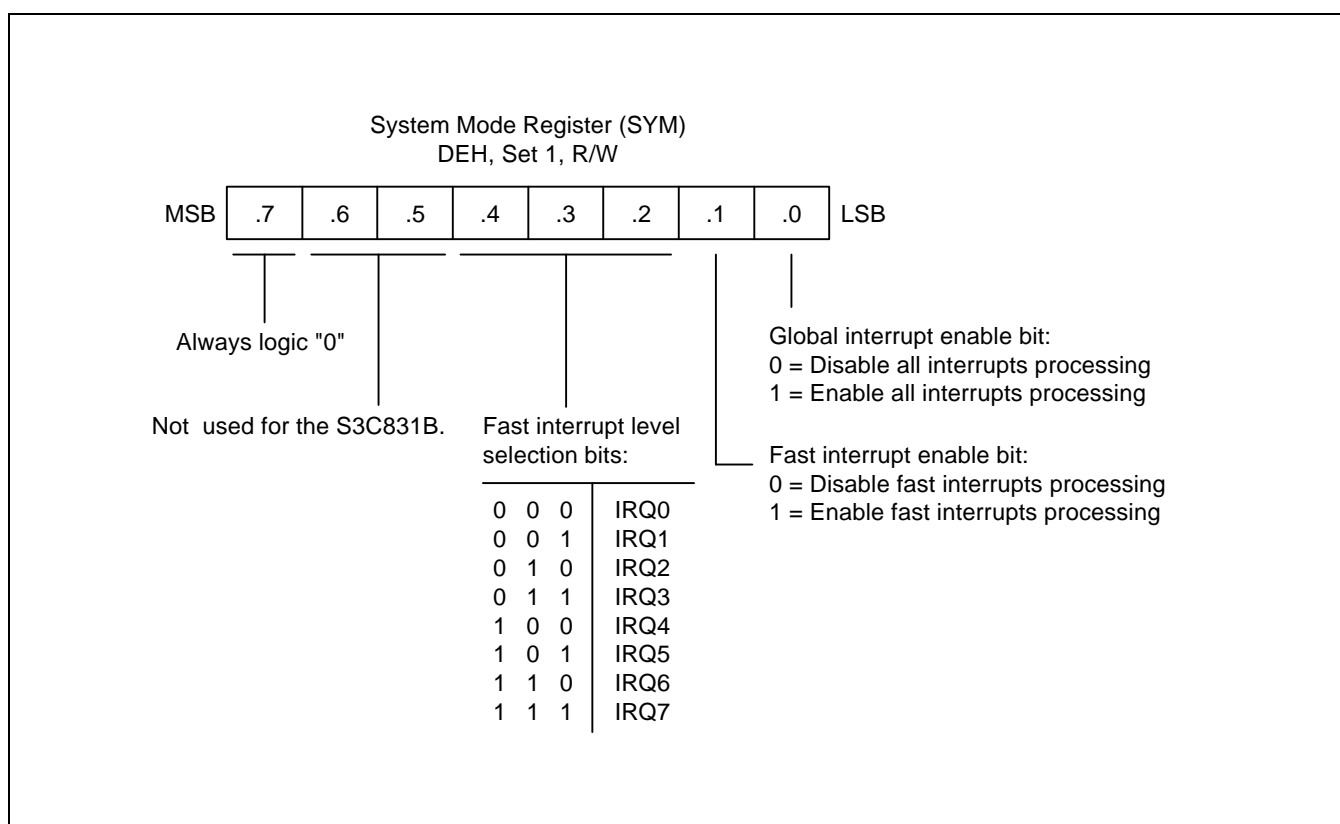

Figure 5-5. System Mode Register (SYM)

INTERRUPT MASK REGISTER (IMR)

The interrupt mask register, IMR (set 1, DDH) is used to enable or disable interrupt processing for individual interrupt levels. After a reset, all IMR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

Each IMR bit corresponds to a specific interrupt level: bit 1 to IRQ1, bit 2 to IRQ2, and so on. When the IMR bit of an interrupt level is cleared to "0", interrupt processing for that level is disabled (masked). When you set a level's IMR bit to "1", interrupt processing for the level is enabled (not masked).

The IMR register is mapped to register location DDH in set 1. Bit values can be read and written by instructions using the Register addressing mode.

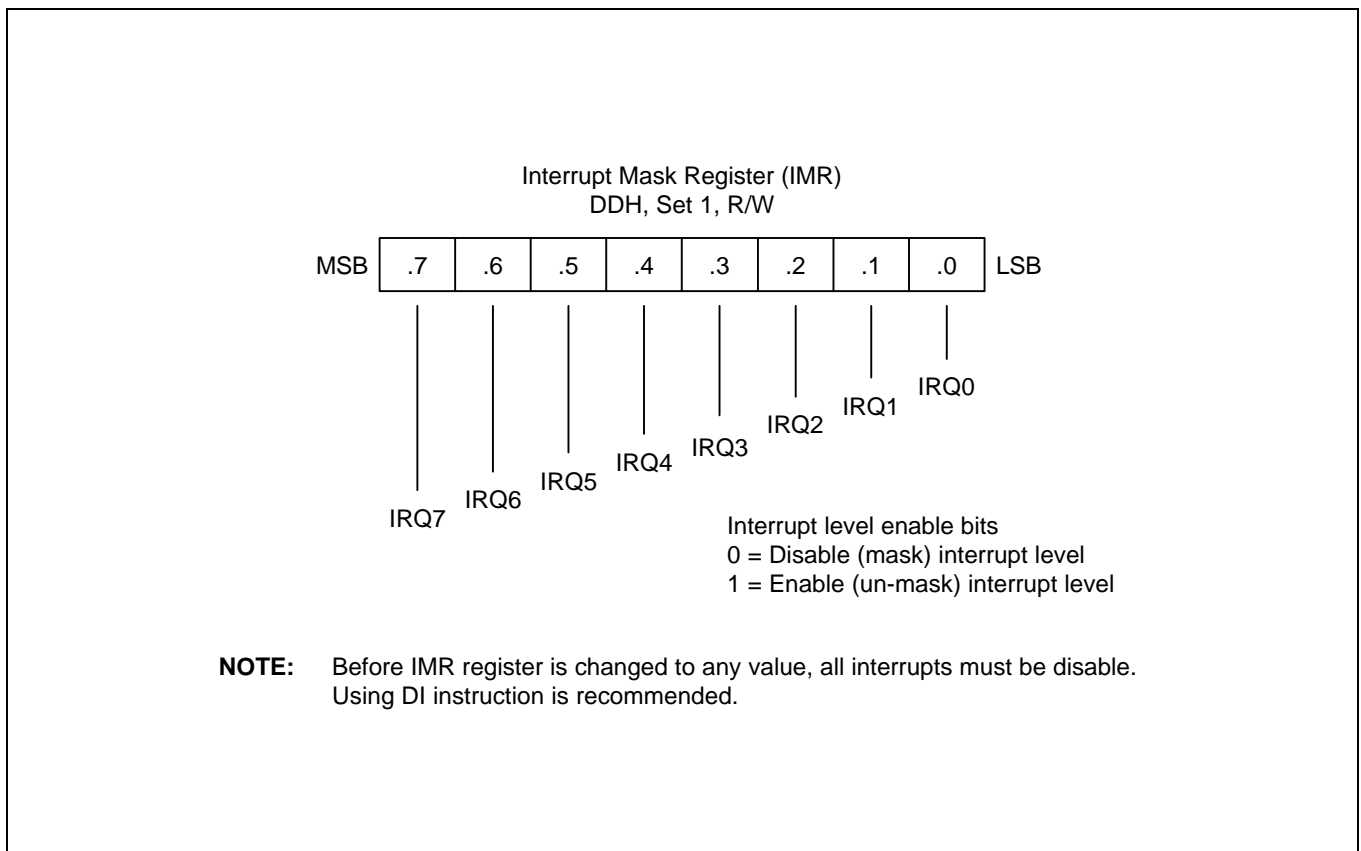

Figure 5-6. Interrupt Mask Register (IMR)

INTERRUPT PRIORITY REGISTER (IPR)

The interrupt priority register, IPR (set 1, bank 0, FFH), is used to set the relative priorities of the interrupt levels in the microcontroller's interrupt structure. After a reset, all IPR bit values are undetermined and must therefore be written to their required settings by the initialization routine.

When more than one interrupt sources are active, the source with the highest priority level is serviced first. If two sources belong to the same interrupt level, the source with the lower vector address usually has the priority (This priority is fixed in hardware).

To support programming of the relative interrupt level priorities, they are organized into groups and subgroups by the interrupt logic. Please note that these groups (and subgroups) are used only by IPR logic for the IPR register priority definitions (see Figure 5-7):

- Group A IRQ0, IRQ1
- Group B IRQ2, IRQ3, IRQ4
- Group C IRQ5, IRQ6, IRQ7

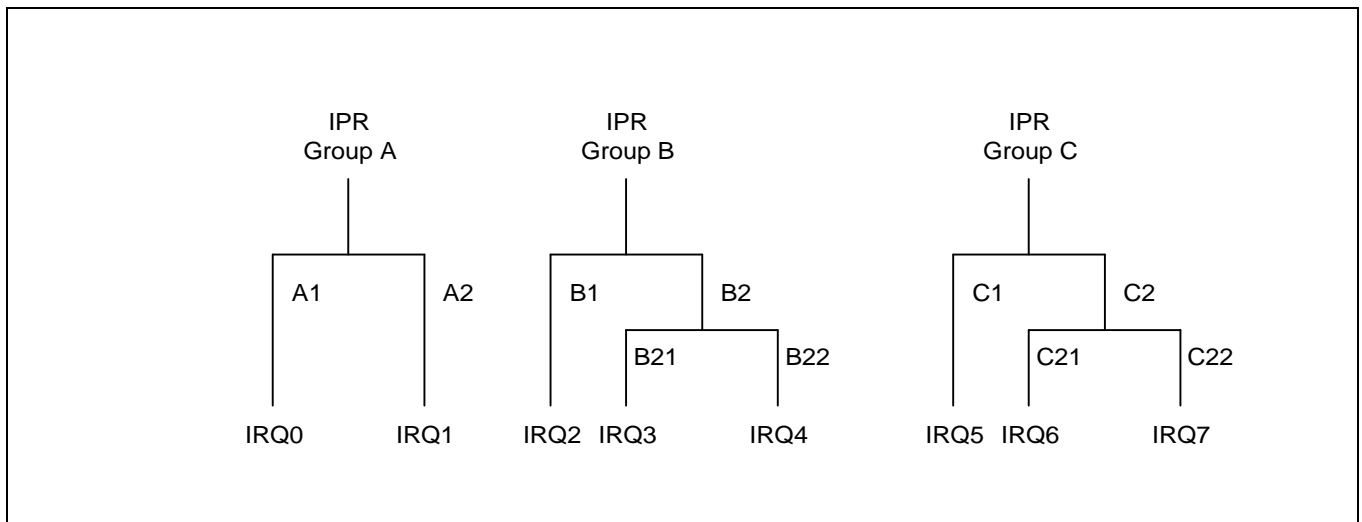

Figure 5-7. Interrupt Request Priority Groups

As you can see in Figure 5-8, IPR.7, IPR.4, and IPR.1 control the relative priority of interrupt groups A, B, and C. For example, the setting "001B" for these bits would select the group relationship B > C > A. The setting "101B" would select the relationship C > B > A.

The functions of the other IPR bit settings are as follows:

- IPR.5 controls the relative priorities of group C interrupts.
- Interrupt group C includes a subgroup that has an additional priority relationship among the interrupt levels 5, 6, and 7. IPR.6 defines the subgroup C relationship. IPR.5 controls the interrupt group C.
- IPR.0 controls the relative priority setting of IRQ0 and IRQ1 interrupts.

Figure 5-8. Interrupt Priority Register (IPR)

INTERRUPT REQUEST REGISTER (IRQ)

You can poll bit values in the interrupt request register, IRQ (set 1, DCH), to monitor interrupt request status for all levels in the microcontroller's interrupt structure. Each bit corresponds to the interrupt level of the same number: bit 0 to IRQ0, bit 1 to IRQ1, and so on. A "0" indicates that no interrupt request is currently being issued for that level. A "1" indicates that an interrupt request has been generated for that level.

IRQ bit values are read-only addressable using Register addressing mode. You can read (test) the contents of the IRQ register at any time using bit or byte addressing to determine the current interrupt request status of specific interrupt levels. After a reset, all IRQ status bits are cleared to “0”.

You can poll IRQ register values even if a DI instruction has been executed (that is, if global interrupt processing is disabled). If an interrupt occurs while the interrupt structure is disabled, the CPU will not service it. You can, however, still detect the interrupt request by polling the IRQ register. In this way, you can determine which events occurred while the interrupt structure was globally disabled.

Figure 5-9. Interrupt Request Register (IRQ)

INTERRUPT PENDING FUNCTION TYPES

Overview

There are two types of interrupt pending bits: one type that is automatically cleared by hardware after the interrupt service routine is acknowledged and executed; the other that must be cleared in the interrupt service routine.

Pending Bits Cleared Automatically by Hardware

For interrupt pending bits that are cleared automatically by hardware, interrupt logic sets the corresponding pending bit to "1" when a request occurs. It then issues an IRQ pulse to inform the CPU that an interrupt is waiting to be serviced. The CPU acknowledges the interrupt source by sending an IACK, executes the service routine, and clears the pending bit to "0". This type of pending bit is not mapped and cannot, therefore, be read or written by application software.

In the S3C831B interrupt structure, the timer 0 overflow interrupt (IRQ0) belongs to this category of interrupts in which pending condition is cleared automatically by hardware.

Pending Bits Cleared by the Service Routine

The second type of pending bit is the one that should be cleared by program software. The service routine must clear the appropriate pending bit before a return-from-interrupt subroutine (IRET) occurs. To do this, a "0" must be written to the corresponding pending bit location in the source's mode or control register.

INTERRUPT SOURCE POLLING SEQUENCE

The interrupt request polling and servicing sequence is as follows:

1. A source generates an interrupt request by setting the interrupt request bit to "1".
2. The CPU polling procedure identifies a pending condition for that source.
3. The CPU checks the source's interrupt level.
4. The CPU generates an interrupt acknowledge signal.
5. Interrupt logic determines the interrupt's vector address.
6. The service routine starts and the source's pending bit is cleared to "0" (by hardware or by software).
7. The CPU continues polling for interrupt requests.

INTERRUPT SERVICE ROUTINES

Before an interrupt request is serviced, the following conditions must be met:

- Interrupt processing must be globally enabled (EI, SYM.0 = "1")
- The interrupt level must be enabled (IMR register)
- The interrupt level must have the highest priority if more than one levels are currently requesting service
- The interrupt must be enabled at the interrupt's source (peripheral control register)

When all the above conditions are met, the interrupt request is acknowledged at the end of the instruction cycle. The CPU then initiates an interrupt machine cycle that completes the following processing sequence:

1. Reset (clear to "0") the interrupt enable bit in the SYM register (SYM.0) to disable all subsequent interrupts.
2. Save the program counter (PC) and status flags to the system stack.
3. Branch to the interrupt vector to fetch the address of the service routine.
4. Pass control to the interrupt service routine.

When the interrupt service routine is completed, the CPU issues an Interrupt Return (IRET). The IRET restores the PC and status flags, setting SYM.0 to "1". It allows the CPU to process the next interrupt request.

GENERATING INTERRUPT VECTOR ADDRESSES

The interrupt vector area in the ROM (00H–FFH) contains the addresses of interrupt service routines that correspond to each level in the interrupt structure. Vectored interrupt processing follows this sequence:

1. Push the program counter's low-byte value to the stack.
2. Push the program counter's high-byte value to the stack.
3. Push the FLAG register values to the stack.
4. Fetch the service routine's high-byte address from the vector location.
5. Fetch the service routine's low-byte address from the vector location.
6. Branch to the service routine specified by the concatenated 16-bit vector address.

NOTE

A 16-bit vector address always begins at an even-numbered ROM address within the range of 00H–FFH.

NESTING OF VECTORED INTERRUPTS

It is possible to nest a higher-priority interrupt request while a lower-priority request is being serviced. To do this, you must follow these steps:

1. Push the current 8-bit interrupt mask register (IMR) value to the stack (PUSH IMR).
2. Load the IMR register with a new mask value that enables only the higher priority interrupt.
3. Execute an EI instruction to enable interrupt processing (a higher priority interrupt will be processed if it occurs).
4. When the lower-priority interrupt service routine ends, restore the IMR to its original value by returning the previous mask value from the stack (POP IMR).
5. Execute an IRET.

Depending on the application, you may be able to simplify the procedure above to some extent.

INSTRUCTION POINTER (IP)

The instruction pointer (IP) is adopted by all the S3C8-series microcontrollers to control the optional high-speed interrupt processing feature called *fast interrupts*. The IP consists of register pair DAH and DBH. The names of IP registers are IPH (high byte, IP15–IP8) and IPL (low byte, IP7–IP0).

FAST INTERRUPT PROCESSING

The feature called *fast interrupt processing* allows an interrupt within a given level to be completed in approximately 6 clock cycles rather than the usual 16 clock cycles. To select a specific interrupt level for fast interrupt processing, you write the appropriate 3-bit value to SYM.4–SYM.2. Then, to enable fast interrupt processing for the selected level, you set SYM.1 to “1”.

FAST INTERRUPT PROCESSING (Continued)

Two other system registers support fast interrupt processing:

- The instruction pointer (IP) contains the starting address of the service routine (and is later used to swap the program counter values), and
- When a fast interrupt occurs, the contents of the FLAGS register is stored in an unmapped, dedicated register called FLAGS' ("FLAGS prime").

NOTE

For the S3C831B microcontroller, the service routine for any one of the eight interrupt levels: IRQ0–IRQ7, can be selected for fast interrupt processing.

Procedure for Initiating Fast Interrupts

To initiate fast interrupt processing, follow these steps:

1. Load the start address of the service routine into the instruction pointer (IP).
2. Load the interrupt level number (IRQn) into the fast interrupt selection field (SYM.4–SYM.2)
3. Write a "1" to the fast interrupt enable bit in the SYM register.

Fast Interrupt Service Routine

When an interrupt occurs in the level selected for fast interrupt processing, the following events occur:

1. The contents of the instruction pointer and the PC are swapped.
2. The FLAG register values are written to the FLAGS' ("FLAGS prime") register.
3. The fast interrupt status bit in the FLAGS register is set.
4. The interrupt is serviced.
5. Assuming that the fast interrupt status bit is set, when the fast interrupt service routine ends, the instruction pointer and PC values are swapped back.
6. The content of FLAGS' ("FLAGS prime") is copied automatically back to the FLAGS register.
7. The fast interrupt status bit in FLAGS is cleared automatically.

Relationship to Interrupt Pending Bit Types

As described previously, there are two types of interrupt pending bits: One type that is automatically cleared by hardware after the interrupt service routine is acknowledged and executed; the other that must be cleared by the application program's interrupt service routine. You can select fast interrupt processing for interrupts with either type of pending condition clear function — by hardware or by software.

Programming Guidelines

Remember that the only way to enable/disable a fast interrupt is to set/clear the fast interrupt enable bit in the SYM register, SYM.1. Executing an EI or DI instruction globally enables or disables all interrupt processing, including fast interrupts. If you use fast interrupts, remember to load the IP with a new start address when the fast interrupt service routine ends.

NOTES

6

INSTRUCTION SET

OVERVIEW

The SAM88RC instruction set is specifically designed to support the large register files that are typical of most SAM8 microcontrollers. There are 78 instructions. The powerful data manipulation capabilities and features of the instruction set include:

- A full complement of 8-bit arithmetic and logic operations, including multiply and divide
- No special I/O instructions (I/O control/data registers are mapped directly into the register file)
- Decimal adjustment included in binary-coded decimal (BCD) operations
- 16-bit (word) data can be incremented and decremented
- Flexible instructions for bit addressing, rotate, and shift operations

DATA TYPES

The SAM8 CPU performs operations on bits, bytes, BCD digits, and two-byte words. Bits in the register file can be set, cleared, complemented, and tested. Bits within a byte are numbered from 7 to 0, where bit 0 is the least significant (right-most) bit.

REGISTER ADDRESSING

To access an individual register, an 8-bit address in the range 0-255 or the 4-bit address of a working register is specified. Paired registers can be used to construct 16-bit data or 16-bit program memory or data memory addresses. For detailed information about register addressing, please refer to Section 2, "Address Spaces."

ADDRESSING MODES

There are seven explicit addressing modes: Register (R), Indirect Register (IR), Indexed (X), Direct (DA), Relative (RA), Immediate (IM), and Indirect (IA). For detailed descriptions of these addressing modes, please refer to Section 3, "Addressing Modes."

SCF		Set carry flag
SRP	src	Set register pointers
SRP0	src	Set register pointer 0
SRP1	src	Set register pointer 1
STOP		Enter Stop mode

FLAGS REGISTER (FLAGS)

The flags register FLAGS contains eight bits that describe the current status of CPU operations. Four of these bits, FLAGS.7–FLAGS.4, can be tested and used with conditional jump instructions; two others FLAGS.3 and FLAGS.2 are used for BCD arithmetic.

The FLAGS register also contains a bit to indicate the status of fast interrupt processing (FLAGS.1) and a bank address status bit (FLAGS.0) to indicate whether bank 0 or bank 1 is currently being addressed. FLAGS register can be set or reset by instructions as long as its outcome does not affect the flags, such as, Load instruction.

Logical and Arithmetic instructions such as, AND, OR, XOR, ADD, and SUB can affect the Flags register. For example, the AND instruction updates the Zero, Sign and Overflow flags based on the outcome of the AND instruction. If the AND instruction uses the Flags register as the destination, then simultaneously, two write will occur to the Flags register producing an unpredictable result.

Figure 6-1. System Flags Register (FLAGS)

FLAG DESCRIPTIONS**C Carry Flag (FLAGS.7)**

The C flag is set to "1" if the result from an arithmetic operation generates a carry-out from or a borrow to the bit 7 position (MSB). After rotate and shift operations, it contains the last value shifted out of the specified register. Program instructions can set, clear, or complement the carry flag.

Z Zero Flag (FLAGS.6)

For arithmetic and logic operations, the Z flag is set to "1" if the result of the operation is zero. For operations that test register bits, and for shift and rotate operations, the Z flag is set to "1" if the result is logic zero.

S Sign Flag (FLAGS.5)

Following arithmetic, logic, rotate, or shift operations, the sign bit identifies the state of the MSB of the result. A logic zero indicates a positive number and a logic one indicates a negative number.

V Overflow Flag (FLAGS.4)

The V flag is set to "1" when the result of a two's-complement operation is greater than + 127 or less than - 128. It is also cleared to "0" following logic operations.

D Decimal Adjust Flag (FLAGS.3)

The DA bit is used to specify what type of instruction was executed last during BCD operations, so that a subsequent decimal adjust operation can execute correctly. The DA bit is not usually accessed by programmers, and cannot be used as a test condition.

H Half-Carry Flag (FLAGS.2)

The H bit is set to "1" whenever an addition generates a carry-out of bit 3, or when a subtraction borrows out of bit 4. It is used by the Decimal Adjust (DA) instruction to convert the binary result of a previous addition or subtraction into the correct decimal (BCD) result. The H flag is seldom accessed directly by a program.

FIS Fast Interrupt Status Flag (FLAGS.1)

The FIS bit is set during a fast interrupt cycle and reset during the IRET following interrupt servicing. When set, it inhibits all interrupts and causes the fast interrupt return to be executed when the IRET instruction is executed.

BA Bank Address Flag (FLAGS.0)

The BA flag indicates which register bank in the set 1 area of the internal register file is currently selected, bank 0 or bank 1. The BA flag is cleared to "0" (select bank 0) when you execute the SB0 instruction and is set to "1" (select bank 1) when you execute the SB1 instruction.

INSTRUCTION SET NOTATION

Table 6-2. Flag Notation Conventions

Flag	Description
C	Carry flag
Z	Zero flag
S	Sign flag
V	Overflow flag
D	Decimal-adjust flag
H	Half-carry flag
0	Cleared to logic zero
1	Set to logic one
*	Set or cleared according to operation
—	Value is unaffected
x	Value is undefined

Table 6-3. Instruction Set Symbols

Symbol	Description
dst	Destination operand
src	Source operand
@	Indirect register address prefix
PC	Program counter
IP	Instruction pointer
FLAGS	Flags register (D5H)
RP	Register pointer
#	Immediate operand or register address prefix
H	Hexadecimal number suffix
D	Decimal number suffix
B	Binary number suffix
opc	Opcode

Table 6-4. Instruction Notation Conventions

Notation	Description	Actual Operand Range
cc	Condition code	See list of condition codes in Table 6-6.
r	Working register only	Rn (n = 0–15)
rb	Bit (b) of working register	Rn.b (n = 0–15, b = 0–7)
r0	Bit 0 (LSB) of working register	Rn (n = 0–15)
rr	Working register pair	RRp (p = 0, 2, 4, ..., 14)
R	Register or working register	reg or Rn (reg = 0–255, n = 0–15)
Rb	Bit 'b' of register or working register	reg.b (reg = 0–255, b = 0–7)
RR	Register pair or working register pair	reg or RRp (reg = 0–254, even number only, where p = 0, 2, ..., 14)
IA	Indirect addressing mode	addr (addr = 0–254, even number only)
Ir	Indirect working register only	@Rn (n = 0–15)
IR	Indirect register or indirect working register	@Rn or @reg (reg = 0–255, n = 0–15)
Irr	Indirect working register pair only	@RRp (p = 0, 2, ..., 14)
IRR	Indirect register pair or indirect working register pair	@RRp or @reg (reg = 0–254, even only, where p = 0, 2, ..., 14)
X	Indexed addressing mode	#reg [Rn] (reg = 0–255, n = 0–15)
XS	Indexed (short offset) addressing mode	#addr [RRp] (addr = range –128 to +127, where p = 0, 2, ..., 14)
xl	Indexed (long offset) addressing mode	#addr [RRp] (addr = range 0–65535, where p = 0, 2, ..., 14)
da	Direct addressing mode	addr (addr = range 0–65535)
ra	Relative addressing mode	addr (addr = number in the range +127 to –128 that is an offset relative to the address of the next instruction)
im	Immediate addressing mode	#data (data = 0–255)
iml	Immediate (long) addressing mode	#data (data = range 0–65535)

CONDITION CODES

The opcode of a conditional jump always contains a 4-bit field called the condition code (cc). This specifies under which conditions it is to execute the jump. For example, a conditional jump with the condition code for "equal" after a compare operation only jumps if the two operands are equal. Condition codes are listed in Table 6-6.

The carry (C), zero (Z), sign (S), and overflow (V) flags are used to control the operation of conditional jump instructions.

Table 6-6. Condition Codes

Binary	Mnemonic	Description	Flags Set
0000	F	Always false	—
1000	T	Always true	—
0111 (note)	C	Carry	C = 1
1111 (note)	NC	No carry	C = 0
0110 (note)	Z	Zero	Z = 1
1110 (note)	NZ	Not zero	Z = 0
1101	PL	Plus	S = 0
0101	MI	Minus	S = 1
0100	OV	Overflow	V = 1
1100	NOV	No overflow	V = 0
0110 (note)	EQ	Equal	Z = 1
1110 (note)	NE	Not equal	Z = 0
1001	GE	Greater than or equal	(S XOR V) = 0
0001	LT	Less than	(S XOR V) = 1
1010	GT	Greater than	(Z OR (S XOR V)) = 0
0010	LE	Less than or equal	(Z OR (S XOR V)) = 1
1111 (note)	UGE	Unsigned greater than or equal	C = 0
0111 (note)	ULT	Unsigned less than	C = 1
1011	UGT	Unsigned greater than	(C = 0 AND Z = 0) = 1
0011	ULE	Unsigned less than or equal	(C OR Z) = 1

NOTES:

1. It indicates condition codes that are related to two different mnemonics but which test the same flag. For example, Z and EQ are both true if the zero flag (Z) is set, but after an ADD instruction, Z would probably be used; after a CP instruction, however, EQ would probably be used.
2. For operations involving unsigned numbers, the special condition codes UGE, ULT, UGT, and ULE must be used.

INSTRUCTION DESCRIPTIONS

This section contains detailed information and programming examples for each instruction in the SAM8 instruction set. Information is arranged in a consistent format for improved readability and for fast referencing. The following information is included in each instruction description:

- Instruction name (mnemonic)
- Full instruction name
- Source/destination format of the instruction operand
- Shorthand notation of the instruction's operation
- Textual description of the instruction's effect
- Specific flag settings affected by the instruction
- Detailed description of the instruction's format, execution time, and addressing mode(s)
- Programming example(s) explaining how to use the instruction

ADC — Add with carry

ADC dst,src

Operation: $\text{dst} \leftarrow \text{dst} + \text{src} + \text{c}$

The source operand, along with the setting of the carry flag, is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed. In multiple precision arithmetic, this instruction permits the carry from the addition of low-order operands to be carried into the addition of high-order operands.

Flags:

- C:** Set if there is a carry from the most significant bit of the result; cleared otherwise.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result is negative; cleared otherwise.
- V:** Set if arithmetic overflow occurs, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.
- D:** Always cleared to "0".
- H:** Set if there is a carry from the most significant bit of the low-order four bits of the result; cleared otherwise.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc		dst src	2	4	12	r r
				6	13	r lr
			3	6	14	R R
opc		src dst		6	15	R IR
			3	6	16	R IM
opc		dst src				

Examples: Given: R1 = 10H, R2 = 03H, C flag = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

ADC	R1,R2	→	R1 = 14H, R2 = 03H
ADC	R1,@R2	→	R1 = 1BH, R2 = 03H
ADC	01H,02H	→	Register 01H = 24H, register 02H = 03H
ADC	01H,@02H	→	Register 01H = 2BH, register 02H = 03H
ADC	01H,#11H	→	Register 01H = 32H

In the first example, destination register R1 contains the value 10H, the carry flag is set to "1", and the source working register R2 contains the value 03H. The statement "ADC R1,R2" adds 03H and the carry flag value ("1") to the destination value 10H, leaving 14H in register R1.

ADD — Add

ADD dst,src

Operation: $\text{dst} \leftarrow \text{dst} + \text{src}$

The source operand is added to the destination operand and the sum is stored in the destination. The contents of the source are unaffected. Two's-complement addition is performed.

Flags:

- C:** Set if there is a carry from the most significant bit of the result; cleared otherwise.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result is negative; cleared otherwise.
- V:** Set if arithmetic overflow occurred, that is, if both operands are of the same sign and the result is of the opposite sign; cleared otherwise.
- D:** Always cleared to "0".
- H:** Set if a carry from the low-order nibble occurred.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div>opc</div> <div>dst src</div>			2	4	02	r	r
				6	03	r	lr
<div>opc</div> <div>src</div> <div>dst</div>			3	6	04	R	R
				6	05	R	IR
<div>opc</div> <div>dst</div> <div>src</div>			3	6	06	R	IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

```

ADD  R1,R2      →   R1 = 15H, R2 = 03H
ADD  R1,@R2     →   R1 = 1CH, R2 = 03H
ADD  01H,02H    →   Register 01H = 24H, register 02H = 03H
ADD  01H,@02H   →   Register 01H = 2BH, register 02H = 03H
ADD  01H,#25H   →   Register 01H = 46H

```

In the first example, destination working register R1 contains 12H and the source working register R2 contains 03H. The statement "ADD R1,R2" adds 03H to 12H, leaving the value 15H in register R1.

AND — Logical AND

AND dst,src

Operation: $\text{dst} \leftarrow \text{dst AND src}$

The source operand is logically ANDed with the destination operand. The result is stored in the destination. The AND operation results in a "1" bit being stored whenever the corresponding bits in the two operands are both logic ones; otherwise a "0" bit value is stored. The contents of the source are unaffected.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always cleared to "0".
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
opc		dst src	2	4	52	r	r
				6	53	r	lr
			3	6	54	R	R
opc		src		dst	6	55	R
			3	6	56	R	IM
opc		dst		src			

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

AND R1,R2 → R1 = 02H, R2 = 03H
AND R1,@R2 → R1 = 02H, R2 = 03H
AND 01H,02H → Register 01H = 01H, register 02H = 03H
AND 01H,@02H → Register 01H = 00H, register 02H = 03H
AND 01H,#25H → Register 01H = 21H

In the first example, destination working register R1 contains the value 12H and the source working register R2 contains 03H. The statement "AND R1,R2" logically ANDs the source operand 03H with the destination operand value 12H, leaving the value 02H in register R1.

BAND — Bit AND

BAND dst,src.b

BAND dst.b,src

Operation: $\text{dst}(0) \leftarrow \text{dst}(0) \text{ AND } \text{src}(b)$
or
 $\text{dst}(b) \leftarrow \text{dst}(b) \text{ AND } \text{src}(0)$

The specified bit of the source (or the destination) is logically ANDed with the zero bit (LSB) of the destination (or source). The resultant bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst b 0	src	3	6	67	r0 Rb
opc	src b 1	dst	3	6	67	Rb r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Examples: Given: R1 = 07H and register 01H = 05H:

BAND R1,01H.1 → R1 = 06H, register 01H = 05H

BAND 01H.1,R1 → Register 01H = 05H, R1 = 07H

In the first example, source register 01H contains the value 05H (00000101B) and destination working register R1 contains 07H (00000111B). The statement "BAND R1,01H.1" ANDs the bit 1 value of the source register ("0") with the bit 0 value of register R1 (destination), leaving the value 06H (00000110B) in register R1.

BCP — Bit Compare

BCP dst,src.b

Operation: dst(0) – src(b)

The specified bit of the source is compared to (subtracted from) bit zero (LSB) of the destination. The zero flag is set if the bits are the same; otherwise it is cleared. The contents of both operands are unaffected by the comparison.

Flags:

- C:** Unaffected.
- Z:** Set if the two bits are the same; cleared otherwise.
- S:** Cleared to "0".
- V:** Undefined.
- D:** Unaffected.
- H:** Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst b 0	src	3	6	17	r0 Rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H and register 01H = 01H:

BCP R1,01H.1 → R1 = 07H, register 01H = 01H

If destination working register R1 contains the value 07H (00000111B) and the source register 01H contains the value 01H (00000001B), the statement "BCP R1,01H.1" compares bit one of the source register (01H) and bit zero of the destination register (R1). Because the bit values are not identical, the zero flag bit (Z) is cleared in the FLAGS register (0D5H).

BITC — Bit Complement

BITC dst.b

Operation: $\text{dst}(b) \leftarrow \text{NOT } \text{dst}(b)$

This instruction complements the specified bit within the destination without affecting any other bits in the destination.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst b 0	2	4	57	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H

BITC R1.1 → R1 = 05H

If working register R1 contains the value 07H (00000111B), the statement "BITC R1.1" complements bit one of the destination and leaves the value 05H (00000101B) in register R1. Because the result of the complement is not "0", the zero flag (Z) in the FLAGS register (0D5H) is cleared.

BITR — Bit Reset

BITR dst.b

Operation: $\text{dst}(b) \leftarrow 0$

The BITR instruction clears the specified bit within the destination without affecting any other bits in the destination.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst b 0	2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITR R1.1 → R1 = 05H

If the value of working register R1 is 07H (00000111B), the statement "BITR R1.1" clears bit one of the destination register R1, leaving the value 05H (00000101B).

BITS — Bit Set

BITS dst.b

Operation: $\text{dst}(b) \leftarrow 1$

The BITS instruction sets the specified bit within the destination without affecting any other bits in the destination.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst b 1	2	4	77	rb

NOTE: In the second byte of the instruction format, the destination address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BITS R1.3 \rightarrow R1 = 0FH

If working register R1 contains the value 07H (00000111B), the statement "BITS R1.3" sets bit three of the destination register R1 to "1", leaving the value 0FH (00001111B).

BOR	dst,src.b
BOR	dst.b,src

The specified bit of the source (or the destination) is logically ORed with bit zero (LSB) of the destination (or the source). The resulting bit value is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
opc	dst b 0	src	3	6	07	r0	Rb
opc	src b 1	dst	3	6	07	Rb	r0

Examples: Given: R1 = 07H and register 01H = 03H:

In the second example, destination register 01H contains the value 03H (00000011B) and the source working register R1 the value 07H (00000111B). The statement "BOR 01H.2,R1" logically ORs bit two of register 01H (destination) with bit zero of R1 (source). This leaves the value 07H in register 01H.

BTJRF — Bit Test, Jump Relative on False

BTJRF dst,src.b

Operation: If src(b) is a "0", then $PC \leftarrow PC + dst$

The specified bit within the source operand is tested. If it is a "0", the relative address is added to the program counter and control passes to the statement whose address is now in the PC; otherwise, the instruction following the BTJRF instruction is executed.

Flags: No flags are affected.

Format:

(Note 1)			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src b 0	dst	3	10	37	RA rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRF SKIP,R1.3 → PC jumps to SKIP location

If working register R1 contains the value 07H (00000111B), the statement "BTJRF SKIP,R1.3" tests bit 3. Because it is "0", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP. (Remember that the memory location must be within the allowed range of + 127 to - 128.)

BTJRT — Bit Test, Jump Relative on True

BTJRT dst,src.b

Operation: If src(b) is a "1", then $PC \leftarrow PC + dst$

The specified bit within the source operand is tested. If it is a "1", the relative address is added to the program counter and control passes to the statement whose address is now in the PC; otherwise, the instruction following the BTJRT instruction is executed.

Flags: No flags are affected.

Format:

(Note 1)			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src b 1	dst	3	10	37	RA rb

NOTE: In the second byte of the instruction format, the source address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Example: Given: R1 = 07H:

BTJRT SKIP,R1.1

If working register R1 contains the value 07H (00000111B), the statement "BTJRT SKIP,R1.1" tests bit one in the source register (R1). Because it is a "1", the relative address is added to the PC and the PC jumps to the memory location pointed to by the SKIP. (Remember that the memory location must be within the allowed range of + 127 to - 128.)

BXOR — Bit XOR

BXOR dst,src.b

BXOR dst.b,src

Operation: $\text{dst}(0) \leftarrow \text{dst}(0) \text{ XOR } \text{src}(b)$
 or
 $\text{dst}(b) \leftarrow \text{dst}(b) \text{ XOR } \text{src}(0)$

The specified bit of the source (or the destination) is logically exclusive-ORed with bit zero (LSB) of the destination (or source). The result bit is stored in the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Cleared to "0".
V: Undefined.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst b 0	src	3	6	27	r0 Rb
opc	src b 1	dst	3	6	27	Rb r0

NOTE: In the second byte of the 3-byte instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Examples: Given: R1 = 07H (00000111B) and register 01H = 03H (00000011B):

BXOR R1,01H.1 → R1 = 06H, register 01H = 03H

BXOR 01H.2,R1 → Register 01H = 07H, R1 = 07H

In the first example, destination working register R1 has the value 07H (00000111B) and source register 01H has the value 03H (00000011B). The statement "BXOR R1,01H.1" exclusive-ORs bit one of register 01H (source) with bit zero of R1 (destination). The result bit value is stored in bit zero of R1, changing its value from 07H to 06H. The value of source register 01H is unaffected.

CALL — Call Procedure

CALL dst

Operation: SP ← SP – 1
 @SP ← PCL
 SP ← SP –1
 @SP ← PCH
 PC ← dst

The current contents of the program counter are pushed onto the top of the stack. The program counter value used is the address of the first instruction following the CALL instruction. The specified destination address is then loaded into the program counter and points to the first instruction of a procedure. At the end of the procedure the return instruction (RET) can be used to return to the original program flow. RET pops the top of the stack back into the program counter.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	3	14	F6	DA
opc	dst	2	12	F4	IRR
opc	dst	2	14	D4	IA

Examples: Given: R0 = 35H, R1 = 21H, PC = 1A47H, and SP = 0002H:

CALL 3521H → SP = 0000H
 (Memory locations 0000H = 1AH, 0001H = 4AH, where
 4AH is the address that follows the instruction.)

CALL @RR0 → SP = 0000H (0000H = 1AH, 0001H = 49H)
CALL #40H → SP = 0000H (0000H = 1AH, 0001H = 49H)

In the first example, if the program counter value is 1A47H and the stack pointer contains the value 0002H, the statement "CALL 3521H" pushes the current PC value onto the top of the stack. The stack pointer now points to memory location 0000H. The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed.

If the contents of the program counter and stack pointer are the same as in the first example, the statement "CALL @RR0" produces the same result except that the 49H is stored in stack location 0001H (because the two-byte instruction format was used). The PC is then loaded with the value 3521H, the address of the first instruction in the program sequence to be executed. Assuming that the contents of the program counter and stack pointer are the same as in the first example, if program address 0040H contains 35H and program address 0041H contains 21H, the statement "CALL #40H" produces the same result as in the second example.

CCF — Complement Carry Flag

CCF

Operation: $C \leftarrow \text{NOT } C$
The carry flag (C) is complemented. If C = "1", the value of the carry flag is changed to logic zero; if C = "0", the value of the carry flag is changed to logic one.

Flags: **C:** Complementated.
No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	EF

Example: Given: The carry flag = "0":

CCF

If the carry flag = "0", the CCF instruction complements it in the FLAGS register (0D5H), changing its value from logic zero to logic one.

CLR — Clear

CLR dst

Operation: $\text{dst} \leftarrow "0"$
The destination location is cleared to "0".

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	B0	R
			4	B1	IR

Examples: Given: Register 00H = 4FH, register 01H = 02H, and register 02H = 5EH:

CLR 00H → Register 00H = 00H

CLR @01H → Register 01H = 02H, register 02H = 00H

In Register (R) addressing mode, the statement "CLR 00H" clears the destination register 00H value to 00H. In the second example, the statement "CLR @01H" uses Indirect Register (IR) addressing mode to clear the 02H register value to 00H.

COM — Complement

COM dst

Operation: dst ← NOT dst

The contents of the destination location are complemented (one's complement); all "1s" are changed to "0s", and vice-versa.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always reset to "0".
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	60	R
			4	61	IR

Examples: Given: R1 = 07H and register 07H = 0F1H:

COM R1 → R1 = 0F8H

COM @R1 → R1 = 07H, register 07H = 0EH

In the first example, destination working register R1 contains the value 07H (00000111B). The statement "COM R1" complements all the bits in R1: all logic ones are changed to logic zeros, and vice-versa, leaving the value 0F8H (11111000B).

In the second example, Indirect Register (IR) addressing mode is used to complement the value of destination register 07H (11110001B), leaving the new value 0EH (00001110B).

CP — Compare

CP dst,src

Operation: dst – src

The source operand is compared to (subtracted from) the destination operand, and the appropriate flags are set accordingly. The contents of both operands are unaffected by the comparison.

Flags: **C:** Set if a "borrow" occurred (src > dst); cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div>opc</div> <div>dst src</div>		2	4	A2	r	r
			6	A3	r	lr
<div>opc</div> <div>src</div> <div>dst</div>		3	6	A4	R	R
			6	A5	R	IR
<div>opc</div> <div>dst</div> <div>src</div>		3	6	A6	R	IM

Examples: 1. Given: R1 = 02H and R2 = 03H:

CP R1,R2 → Set the C and S flags

Destination working register R1 contains the value 02H and source register R2 contains the value 03H. The statement "CP R1,R2" subtracts the R2 value (source/subtrahend) from the R1 value (destination/minuend). Because a "borrow" occurs and the difference is negative, C and S are "1".

2. Given: R1 = 05H and R2 = 0AH:

```

CP    R1,R2
JP    UGE,SKIP
INC   R1
SKIP  LD    R3,R1

```

In this example, destination working register R1 contains the value 05H which is less than the contents of the source working register R2 (0AH). The statement "CP R1,R2" generates C = "1" and the JP instruction does not jump to the SKIP location. After the statement "LD R3,R1" executes, the value 06H remains in working register R3.

CPIJE — Compare, Increment, and Jump on Equal

CPIJE dst,src,RA

Operation: If $\text{dst} - \text{src} = "0"$, $\text{PC} \leftarrow \text{PC} + \text{RA}$
 $\text{lr} \leftarrow \text{lr} + 1$

The source operand is compared to (subtracted from) the destination operand. If the result is "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter. Otherwise, the instruction immediately following the CPIJE instruction is executed. In either case, the source pointer is incremented by one before the next instruction is executed.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src	dst	RA	3	12	C2	r lr

NOTE: Execution time is 18 cycles if the jump is taken or 16 cycles if it is not taken.

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 02H:

CPIJE R1,@R2,SKIP → R2 = 04H, PC jumps to SKIP location

In this example, working register R1 contains the value 02H, working register R2 the value 03H, and register 03 contains 02H. The statement "CPIJE R1,@R2,SKIP" compares the @R2 value 02H (00000010B) to 02H (00000010B). Because the result of the comparison is *equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source register (R2) is incremented by one, leaving a value of 04H. (Remember that the memory location must be within the allowed range of +127 to -128.)

CPIJNE — Compare, Increment, and Jump on Non-Equal

CPIJNE dst,src,RA

Operation: If dst – src = "0", PC ← PC + RA
 lr ← lr + 1

The source operand is compared to (subtracted from) the destination operand. If the result is not "0", the relative address is added to the program counter and control passes to the statement whose address is now in the program counter; otherwise the instruction following the CPIJNE instruction is executed. In either case the source pointer is incremented by one before the next instruction.

Flags: No flags are affected.

Format:

				Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>				
<table><tr><td>opc</td><td>src</td><td>dst</td><td>RA</td></tr></table>				opc	src	dst	RA	3	12	D2	r lr
opc	src	dst	RA								

NOTE: Execution time is 18 cycles if the jump is taken or 16 cycles if it is not taken.

Example: Given: R1 = 02H, R2 = 03H, and register 03H = 04H:

CPIJNE R1,@R2,SKIP → R2 = 04H, PC jumps to SKIP location

Working register R1 contains the value 02H, working register R2 (the source pointer) the value 03H, and general register 03 the value 04H. The statement "CPIJNE R1,@R2,SKIP" subtracts 04H (00000100B) from 02H (00000010B). Because the result of the comparison is *non-equal*, the relative address is added to the PC and the PC then jumps to the memory location pointed to by SKIP. The source pointer register (R2) is also incremented by one, leaving a value of 04H. (Remember that the memory location must be within the allowed range of + 127 to – 128.)

DA — Decimal Adjust

DA dst

Operation: dst ← DA dst

The destination operand is adjusted to form two 4-bit BCD digits following an addition or subtraction operation. For addition (ADD, ADC) or subtraction (SUB, SBC), the following table indicates the operation performed. (The operation is undefined if the destination operand was not the result of a valid addition or subtraction of BCD digits):

Instruction	Carry Before DA	Bits 4–7 Value (Hex)	H Flag Before DA	Bits 0–3 Value (Hex)	Number Added to Byte	Carry After DA
ADD ADC	0	0–9	0	0–9	00	0
	0	0–8	0	A–F	06	0
	0	0–9	1	0–3	06	0
	0	A–F	0	0–9	60	1
	0	9–F	0	A–F	66	1
	0	A–F	1	0–3	66	1
	1	0–2	0	0–9	60	1
	1	0–2	0	A–F	66	1
	1	0–3	1	0–3	66	1
SUB SBC	0	0–9	0	0–9	00 = – 00	0
	0	0–8	1	6–F	FA = – 06	0
	1	7–F	0	0–9	A0 = – 60	1
	1	6–F	1	6–F	9A = – 66	1

Flags:

- C:** Set if there was a carry from the most significant bit; cleared otherwise (see table).
- Z:** Set if result is "0"; cleared otherwise.
- S:** Set if result bit 7 is set; cleared otherwise.
- V:** Undefined.
- D:** Unaffected.
- H:** Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
<div>opc dst</div>		2	4	40	R
			4	41	IR

DA — Decimal Adjust

DA (Continued)

Example: Given: Working register R0 contains the value 15 (BCD), working register R1 contains 27 (BCD), and address 27H contains 46 (BCD):

```
ADD    R1,R0      ;    C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = C, R1 ← 3CH
DA     R1          ;    R1 ← 3CH + 06
```

If addition is performed using the BCD values 15 and 27, the result should be 42. The sum is incorrect, however, when the binary representations are added in the destination location using standard binary arithmetic:

$$\begin{array}{r} 0001\ 0101 \quad 15 \\ + 0010\ 0111 \quad 27 \\ \hline 0011\ 1100 = 3CH \end{array}$$

The DA instruction adjusts this result so that the correct BCD representation is obtained:

$$\begin{array}{r} 0011\ 1100 \\ + 0000\ 0110 \\ \hline 0100\ 0010 = 42 \end{array}$$

Assuming the same values given above, the statements

```
SUB    27H,R0;      C ← "0", H ← "0", Bits 4–7 = 3, bits 0–3 = 1
DA     @R1 ;        @R1 ← 31–0
```

leave the value 31 (BCD) in address 27H (@R1).

DEC — Decrement

DEC dst

Operation: $\text{dst} \leftarrow \text{dst} - 1$

The contents of the destination operand are decremented by one.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if result is negative; cleared otherwise.
V: Set if arithmetic overflow occurred; cleared otherwise.
D: Unaffected.
H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	00	R
			4	01	IR

Examples: Given: R1 = 03H and register 03H = 10H:

DEC R1 → R1 = 02H

DEC @R1 → Register 03H = 0FH

In the first example, if working register R1 contains the value 03H, the statement "DEC R1" decrements the hexadecimal value by one, leaving the value 02H. In the second example, the statement "DEC @R1" decrements the value 10H contained in the destination register 03H by one, leaving the value 0FH.

DECW — Decrement Word

DECW dst

Operation: $\text{dst} \leftarrow \text{dst} - 1$

The contents of the destination location (which must be an even address) and the operand following that location are treated as a single 16-bit value that is decremented by one.

Flags: **C:** Unaffected.
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result is negative; cleared otherwise.
 V: Set if arithmetic overflow occurred; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	8	80	RR
			8	81	IR

Examples: Given: R0 = 12H, R1 = 34H, R2 = 30H, register 30H = 0FH, and register 31H = 21H:

DECW RR0 → R0 = 12H, R1 = 33H

DECW @R2 → Register 30H = 0FH, register 31H = 20H

In the first example, destination register R0 contains the value 12H and register R1 the value 34H. The statement "DECW RR0" addresses R0 and the following operand R1 as a 16-bit word and decrements the value of R1 by one, leaving the value 33H.

NOTE: A system malfunction may occur if you use a Zero flag (FLAGS.6) result together with a DECW instruction. To avoid this problem, we recommend that you use DECW as shown in the following example:

```
LOOP: DECW RR0
      LD   R2,R1
      OR   R2,R0
      JR   NZ,LOOP
```

DI — Disable Interrupts

DI

Operation: $SYM(0) \leftarrow 0$
Bit zero of the system mode control register, SYM.0, is cleared to "0", globally disabling all interrupt processing. Interrupt requests will continue to set their respective interrupt pending bits, but the CPU will not service them while interrupt processing is disabled.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	8F

Example: Given: SYM = 01H:

DI

If the value of the SYM register is 01H, the statement "DI" leaves the new value 00H in the register and clears SYM.0 to "0", disabling interrupt processing.

Before changing IMR, interrupt pending and interrupt source control register, be sure DI state.

DIV — Divide (Unsigned)

DIV dst,src

Operation: $\text{dst} \div \text{src}$
 dst (UPPER) \leftarrow REMAINDER
 dst (LOWER) \leftarrow QUOTIENT

The destination operand (16 bits) is divided by the source operand (8 bits). The quotient (8 bits) is stored in the lower half of the destination. The remainder (8 bits) is stored in the upper half of the destination. When the quotient is $\geq 2^8$, the numbers stored in the upper and lower halves of the destination for quotient and remainder are incorrect. Both operands are treated as unsigned integers.

Flags: **C:** Set if the V flag is set and quotient is between 2^8 and $2^9 - 1$; cleared otherwise.
 Z: Set if divisor or quotient = "0"; cleared otherwise.
 S: Set if MSB of quotient = "1"; cleared otherwise.
 V: Set if quotient is $\geq 2^8$ or if divisor = "0"; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src	dst	3	26/10	94	RR R
				26/10	95	RR IR
				26/10	96	RR IM

NOTE: Execution takes 10 cycles if the divide-by-zero is attempted; otherwise it takes 26 cycles.

Examples: Given: R0 = 10H, R1 = 03H, R2 = 40H, register 40H = 80H:

DIV RR0,R2 \rightarrow R0 = 03H, R1 = 40H
 DIV RR0,@R2 \rightarrow R0 = 03H, R1 = 20H
 DIV RR0,#20H \rightarrow R0 = 03H, R1 = 80H

In the first example, destination working register pair RR0 contains the values 10H (R0) and 03H (R1), and register R2 contains the value 40H. The statement "DIV RR0,R2" divides the 16-bit RR0 value by the 8-bit value of the R2 (source) register. After the DIV instruction, R0 contains the value 03H and R1 contains 40H. The 8-bit remainder is stored in the upper half of the destination register RR0 (R0) and the quotient in the lower half (R1).

DJNZ — Decrement and Jump if Non-Zero

DJNZ r,dst

Operation: $r \leftarrow r - 1$
 If $r \neq 0$, $PC \leftarrow PC + dst$

The working register being used as a counter is decremented. If the contents of the register are not logic zero after decrementing, the relative address is added to the program counter and control passes to the statement whose address is now in the PC. The range of the relative address is +127 to -128, and the original value of the PC is taken to be the address of the instruction byte following the DJNZ statement.

NOTE: In case of using DJNZ instruction, the working register being used as a counter should be set at the one of location 0C0H to 0CFH with SRP, SRP0, or SRP1 instruction.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>	
<table border="1"><tr><td>r</td><td>opc</td><td>dst</td></tr></table>	r	opc	dst	2	8 (jump taken)	rA	RA
	r	opc	dst				
8 (no jump)	r = 0 to F						

Example: Given: R1 = 02H and LOOP is the label of a relative address:

```
SRP    #0C0H
DJNZ   R1,LOOP
```

DJNZ is typically used to control a "loop" of instructions. In many cases, a label is used as the destination operand instead of a numeric relative address value. In the example, working register R1 contains the value 02H, and LOOP is the label for a relative address.

The statement "DJNZ R1, LOOP" decrements register R1 by one, leaving the value 01H. Because the contents of R1 after the decrement are non-zero, the jump is taken to the relative address specified by the LOOP label.

EI — Enable Interrupts

EI

Operation: $SYM(0) \leftarrow 1$

An EI instruction sets bit zero of the system mode register, SYM.0 to "1". This allows interrupts to be serviced as they occur (assuming they have highest priority). If an interrupt's pending bit was set while interrupt processing was disabled (by executing a DI instruction), it will be serviced when you execute the EI instruction.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	9F

Example: Given: SYM = 00H:

EI

If the SYM register contains the value 00H, that is, if interrupts are currently disabled, the statement "EI" sets the SYM register to 01H, enabling all interrupts. (SYM.0 is the enable bit for global interrupt processing.)

ENTER — Enter

ENTER

Operation:

SP

←

SP – 2

@SP

←

IP

IP

←

PC

PC

←

@IP

IP

←

IP + 2

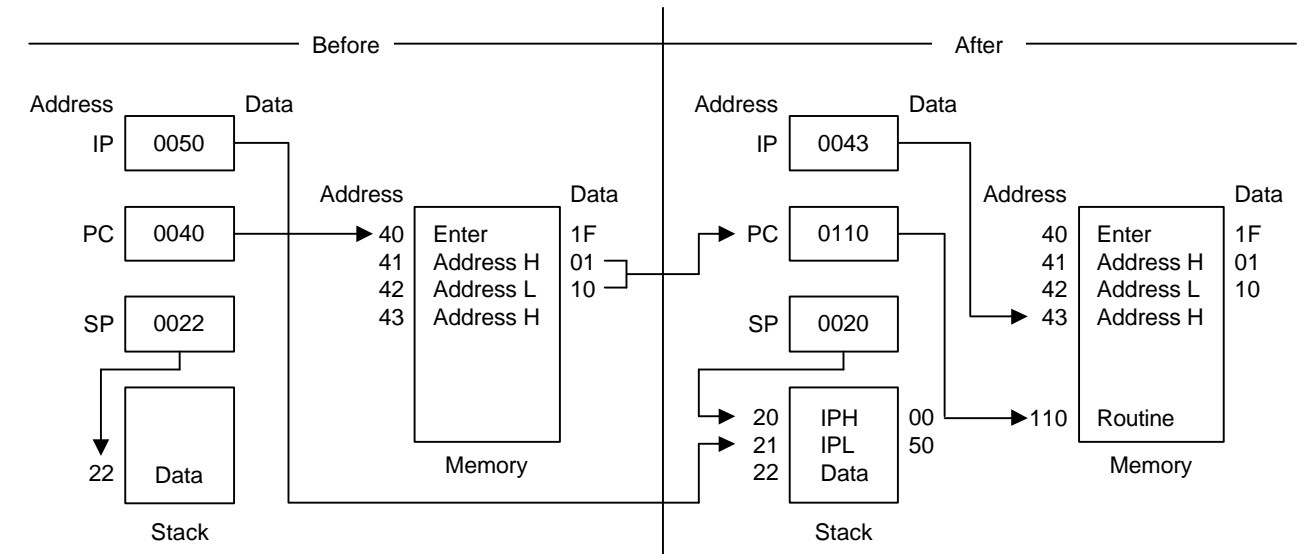

This instruction is useful when implementing threaded-code languages. The contents of the instruction pointer are pushed to the stack. The program counter (PC) value is then written to the instruction pointer. The program memory word that is pointed to by the instruction pointer is loaded into the PC, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	14	1F

Example: The diagram below shows one example of how to use an ENTER statement.

EXIT — Exit

EXIT

Operation:

IP

←

@SP

SP

←

SP + 2

PC

←

@IP

IP

←

IP + 2

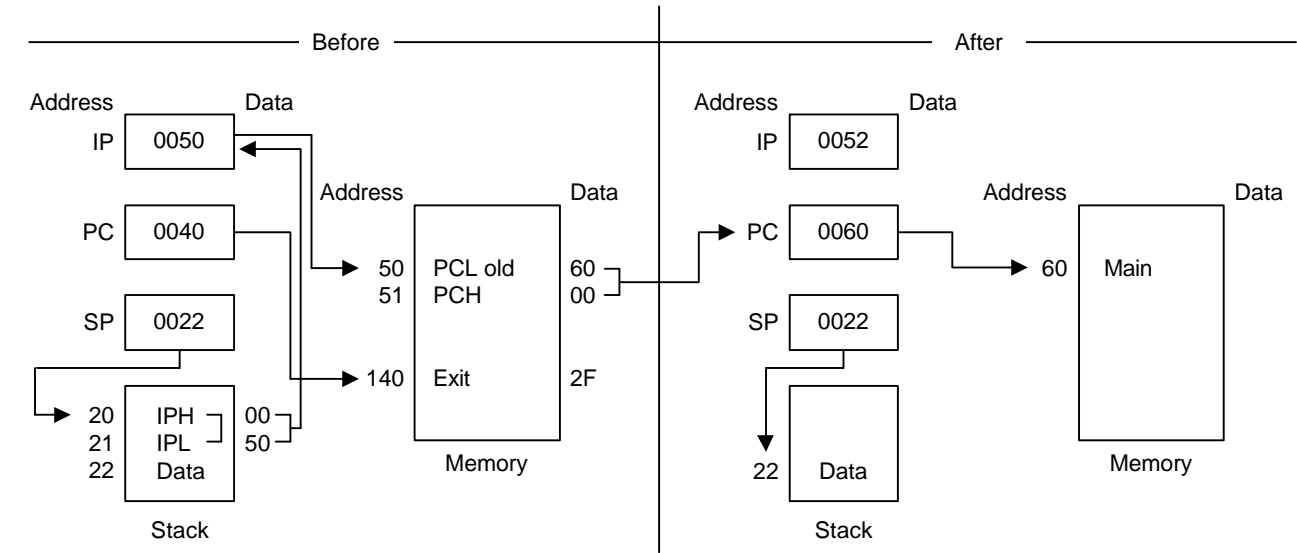

This instruction is useful when implementing threaded-code languages. The stack value is popped and loaded into the instruction pointer. The program memory word that is pointed to by the instruction pointer is then loaded into the program counter, and the instruction pointer is incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	14 (internal stack) 16 (internal stack)	2F

Example: The diagram below shows one example of how to use an EXIT statement.

IDLE — Idle Operation

IDLE

Operation:

The IDLE instruction stops the CPU clock while allowing system clock oscillation to continue. Idle mode can be released by an interrupt request (IRQ) or an external reset operation. In application programs, a IDLE instruction must be immediately followed by at least three NOP instructions. This ensures an adequate time interval for the clock to stabilize before the next instruction is executed. If three or more NOP instructions are not used after IDLE instruction, leakage current could be flown because of the floating state in the internal bus.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div>opc</div>	1	4	6F	—	—

Example:

The instruction

IDLE

NOP

NOP

NOP

; stops the CPU clock but not the system clock

INC — Increment

INC dst

Operation: $\text{dst} \leftarrow \text{dst} + 1$
The contents of the destination operand are incremented by one.

Flags: **C:** Unaffected.
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result is negative; cleared otherwise.
 V: Set if arithmetic overflow occurred; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
<div>dst opc</div>		1	4	rE	r
		r = 0 to F			
<div>opc dst</div>		2	4	20	R
			4	21	IR

Examples: Given: R0 = 1BH, register 00H = 0CH, and register 1BH = 0FH:

INC R0 → R0 = 1CH
INC 00H → Register 00H = 0DH
INC @R0 → R0 = 1BH, register 01H = 10H

In the first example, if destination working register R0 contains the value 1BH, the statement "INC R0" leaves the value 1CH in that same register.

The next example shows the effect an INC instruction has on register 00H, assuming that it contains the value 0CH.

In the third example, INC is used in Indirect Register (IR) addressing mode to increment the value of register 1BH from 0FH to 10H.

INCW — Increment Word

INCW dst

Operation: $\text{dst} \leftarrow \text{dst} + 1$

The contents of the destination (which must be an even address) and the byte following that location are treated as a single 16-bit value that is incremented by one.

Flags:

- C:** Unaffected.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result is negative; cleared otherwise.
- V:** Set if arithmetic overflow occurred; cleared otherwise.
- D:** Unaffected.
- H:** Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode
					<u>dst</u>
opc	dst	2	8	A0	RR
			8	A1	IR

Examples: Given: R0 = 1AH, R1 = 02H, register 02H = 0FH, and register 03H = 0FFH:

INCW RR0 → R0 = 1AH, R1 = 03H

INCW @R1 → Register 02H = 10H, register 03H = 00H

In the first example, the working register pair RR0 contains the value 1AH in register R0 and 02H in register R1. The statement "INCW RR0" increments the 16-bit destination by one, leaving the value 03H in register R1. In the second example, the statement "INCW @R1" uses Indirect Register (IR) addressing mode to increment the contents of general register 03H from 0FFH to 00H and register 02H from 0FH to 10H.

NOTE: A system malfunction may occur if you use a Zero (Z) flag (FLAGS.6) result together with an INCW instruction. To avoid this problem, we recommend that you use INCW as shown in the following example:

```

LOOP:  INCW   RR0
        LD    R2,R1
        OR    R2,R0
        JR    NZ,LOOP

```

IRET — Interrupt Return

IRET	<u>IRET (Normal)</u>	<u>IRET (Fast)</u>
Operation:	$\text{FLAGS} \leftarrow @\text{SP}$ $\text{SP} \leftarrow \text{SP} + 1$ $\text{PC} \leftarrow @\text{SP}$ $\text{SP} \leftarrow \text{SP} + 2$ $\text{SYM}(0) \leftarrow 1$	$\text{PC} \leftrightarrow \text{IP}$ $\text{FLAGS} \leftarrow \text{FLAGS}'$ $\text{FIS} \leftarrow 0$

This instruction is used at the end of an interrupt service routine. It restores the flag register and the program counter. It also re-enables global interrupts. A "normal IRET" is executed only if the fast interrupt status bit (FIS, bit one of the FLAGS register, 0D5H) is cleared (= "0"). If a fast interrupt occurred, IRET clears the FIS bit that was set at the beginning of the service routine.

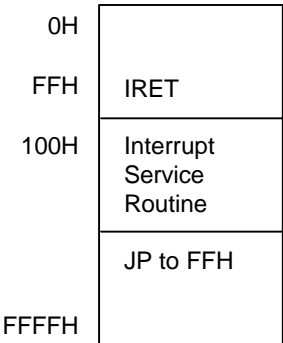

Flags: All flags are restored to their original settings (that is, the settings before the interrupt occurred).

Format:

IRET (Normal)	Bytes	Cycles	Opcode (Hex)
opc	1	10 (internal stack) 12 (internal stack)	BF

IRET (Fast)	Bytes	Cycles	Opcode (Hex)
opc	1	6	BF

Example: In the figure below, the instruction pointer is initially loaded with 100H in the main program before interrupts are enabled. When an interrupt occurs, the program counter and instruction pointer are swapped. This causes the PC to jump to address 100H and the IP to keep the return address. The last instruction in the service routine normally is a jump to IRET at address FFH. This causes the instruction pointer to be loaded with 100H "again" and the program counter to jump back to the main program. Now, the next interrupt can occur and the IP is still correct at 100H.

NOTE: In the fast interrupt example above, if the last instruction is not a jump to IRET, you must pay attention to the order of the last two instructions. The IRET cannot be immediately proceeded by a clearing of the interrupt status (as with a reset of the IPR register).

JP — Jump

JP cc,dst (Conditional)

JP dst (Unconditional)

Operation: If cc is true, $PC \leftarrow dst$

The conditional JUMP instruction transfers program control to the destination address if the condition specified by the condition code (cc) is true; otherwise, the instruction following the JP instruction is executed. The unconditional JP simply replaces the contents of the PC with the contents of the specified register pair. Control then passes to the statement addressed by the PC.

Flags: No flags are affected.

Format: ⁽¹⁾

(2)			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
<div>cc opc dst</div>			3	8	ccD	DA
					cc = 0 to F	
<div>opc dst</div>			2	8	30	IRR

NOTES:

1. The 3-byte format is used for a conditional jump and the 2-byte format for an unconditional jump.
2. In the first byte of the three-byte instruction format (conditional jump), the condition code and the opcode are both four bits.

Examples: Given: The carry flag (C) = "1", register 00 = 01H, and register 01 = 20H:

JP C,LABEL_W → LABEL_W = 1000H, PC = 1000H

JP @00H → PC = 0120H

The first example shows a conditional JP. Assuming that the carry flag is set to "1", the statement

"JP C,LABEL_W" replaces the contents of the PC with the value 1000H and transfers control to that location. Had the carry flag not been set, control would then have passed to the statement immediately following the JP instruction.

The second example shows an unconditional JP. The statement "JP @00" replaces the contents of the PC with the contents of the register pair 00H and 01H, leaving the value 0120H.

JR — Jump Relative

JR cc,dst

Operation: If cc is true, $PC \leftarrow PC + dst$

If the condition specified by the condition code (cc) is true, the relative address is added to the program counter and control passes to the statement whose address is now in the program counter; otherwise, the instruction following the JR instruction is executed. (See list of condition codes).

The range of the relative address is +127, -128, and the original value of the program counter is taken to be the address of the first instruction byte following the JR statement.

Flags: No flags are affected.

Format:

(1)		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
cc opc	dst	2	6	ccB	RA
		cc = 0 to F			

NOTE: In the first byte of the two-byte instruction format, the condition code and the opcode are each four bits.

Example: Given: The carry flag = "1" and LABEL_X = 1FF7H:

JR C,LABEL_X → PC = 1FF7H

If the carry flag is set (that is, if the condition code is true), the statement "JR C,LABEL_X" will pass control to the statement whose address is now in the PC. Otherwise, the program instruction following the JR would be executed.

LD — Load

LDdst,src

Operation:

dst ← src

The contents of the source are loaded into the destination. The source's contents are unaffected.

Flags:

No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
dst opc		src	2	4	rC	r	IM
				4	r8	r	R
src opc		dst	2	4	r9	R	r
					r = 0 to F		
opc	dst src		2	4	C7	r	lr
				4	D7	lr	r
opc	src	dst	3	6	E4	R	R
				6	E5	R	IR
opc	dst	src	3	6	E6	R	IM
				6	D6	IR	IM
opc	src	dst	3	6	F5	IR	R
opc	dst src	x	3	6	87	r	x[r]
opc	src dst	x	3	6	97	x[r]	r

LD — Load

LD (Continued)

Examples: Given: R0 = 01H, R1 = 0AH, register 00H = 01H, register 01H = 20H, register 02H = 02H, LOOP = 30H, and register 3AH = 0FFH:

LD	R0,#10H	→	R0 = 10H
LD	R0,01H	→	R0 = 20H, register 01H = 20H
LD	01H,R0	→	Register 01H = 01H, R0 = 01H
LD	R1,@R0	→	R1 = 20H, R0 = 01H
LD	@R0,R1	→	R0 = 01H, R1 = 0AH, register 01H = 0AH
LD	00H,01H	→	Register 00H = 20H, register 01H = 20H
LD	02H,@00H	→	Register 02H = 20H, register 00H = 01H
LD	00H,#0AH	→	Register 00H = 0AH
LD	@00H,#10H	→	Register 00H = 01H, register 01H = 10H
LD	@00H,02H	→	Register 00H = 01H, register 01H = 02, register 02H = 02H
LD	R0,#LOOP[R1]	→	R0 = 0FFH, R1 = 0AH
LD	#LOOP[R0],R1	→	Register 31H = 0AH, R0 = 01H, R1 = 0AH

LDB — Load Bit

LDB dst,src.b

LDB dst.b,src

Operation: $\text{dst}(0) \leftarrow \text{src}(b)$
 or
 $\text{dst}(b) \leftarrow \text{src}(0)$

The specified bit of the source is loaded into bit zero (LSB) of the destination, or bit zero of the source is loaded into the specified bit of the destination. No other bits of the destination are affected. The source is unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst b 0	src	3	6	47	r0 Rb
opc	src b 1	dst	3	6	47	Rb r0

NOTE: In the second byte of the instruction formats, the destination (or source) address is four bits, the bit address 'b' is three bits, and the LSB address value is one bit in length.

Examples: Given: R0 = 06H and general register 00H = 05H:

LDB R0,00H.2 → R0 = 07H, register 00H = 05H

LDB 00H.0,R0 → R0 = 06H, register 00H = 04H

In the first example, destination working register R0 contains the value 06H and the source general register 00H the value 05H. The statement "LD R0,00H.2" loads the bit two value of the 00H register into bit zero of the R0 register, leaving the value 07H in register R0.

In the second example, 00H is the destination register. The statement "LD 00H.0,R0" loads bit zero of register R0 to the specified bit (bit zero) of the destination register, leaving 04H in general register 00H.

LDC/LDE — Load Memory

LDC/LDE dst,src

Operation: dst ← src

This instruction loads a byte from program or data memory into a working register or vice-versa. The source values are unaffected. LDC refers to program memory and LDE to data memory. The assembler makes 'lrr' or 'rr' values an even number for program memory and odd an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>				
1.	<table><tr><td>opc</td><td>dst src</td></tr></table>	opc	dst src	2	10	C3	r	lrr		
opc	dst src									
2.	<table><tr><td>opc</td><td>src dst</td></tr></table>	opc	src dst	2	10	D3	lrr	r		
opc	src dst									
3.	<table><tr><td>opc</td><td>dst src</td><td>XS</td></tr></table>	opc	dst src	XS	3	12	E7	r	XS [rr]	
opc	dst src	XS								
4.	<table><tr><td>opc</td><td>src dst</td><td>XS</td></tr></table>	opc	src dst	XS	3	12	F7	XS [rr]	r	
opc	src dst	XS								
5.	<table><tr><td>opc</td><td>dst src</td><td>XL_L</td><td>XL_H</td></tr></table>	opc	dst src	XL _L	XL _H	4	14	A7	r	XL [rr]
opc	dst src	XL _L	XL _H							
6.	<table><tr><td>opc</td><td>src dst</td><td>XL_L</td><td>XL_H</td></tr></table>	opc	src dst	XL _L	XL _H	4	14	B7	XL [rr]	r
opc	src dst	XL _L	XL _H							
7.	<table><tr><td>opc</td><td>dst 0000</td><td>DA_L</td><td>DA_H</td></tr></table>	opc	dst 0000	DA _L	DA _H	4	14	A7	r	DA
opc	dst 0000	DA _L	DA _H							
8.	<table><tr><td>opc</td><td>src 0000</td><td>DA_L</td><td>DA_H</td></tr></table>	opc	src 0000	DA _L	DA _H	4	14	B7	DA	r
opc	src 0000	DA _L	DA _H							
9.	<table><tr><td>opc</td><td>dst 0001</td><td>DA_L</td><td>DA_H</td></tr></table>	opc	dst 0001	DA _L	DA _H	4	14	A7	r	DA
opc	dst 0001	DA _L	DA _H							
10.	<table><tr><td>opc</td><td>src 0001</td><td>DA_L</td><td>DA_H</td></tr></table>	opc	src 0001	DA _L	DA _H	4	14	B7	DA	r
opc	src 0001	DA _L	DA _H							

NOTES:

1. The source (src) or working register pair [rr] for formats 5 and 6 cannot use register pair 0–1.
2. For formats 3 and 4, the destination address 'XS [rr]' and the source address 'XS [rr]' are each one byte.
3. For formats 5 and 6, the destination address 'XL [rr]' and the source address 'XL [rr]' are each two bytes.
4. The DA and r source values for formats 7 and 8 are used to address program memory; the second set of values, used in formats 9 and 10, are used to address data memory.

LDC/LDE — Load Memory

LDC/LDE (Continued)

Examples: Given: R0 = 11H, R1 = 34H, R2 = 01H, R3 = 04H; Program memory locations 0103H = 4FH, 0104H = 1A, 0105H = 6DH, and 1104H = 88H. External data memory locations 0103H = 5FH, 0104H = 2AH, 0105H = 7DH, and 1104H = 98H:

LDC	R0,@RR2	; R0 ← contents of program memory location 0104H ; R0 = 1AH, R2 = 01H, R3 = 04H
LDE	R0,@RR2	; R0 ← contents of external data memory location 0104H ; R0 = 2AH, R2 = 01H, R3 = 04H
LDC (note)	@RR2,R0	; 11H (contents of R0) is loaded into program memory ; location 0104H (RR2), ; working registers R0, R2, R3 → no change
LDE	@RR2,R0	; 11H (contents of R0) is loaded into external data memory ; location 0104H (RR2), ; working registers R0, R2, R3 → no change
LDC	R0,#01H[RR2]	; R0 ← contents of program memory location 0105H ; (01H + RR2), ; R0 = 6DH, R2 = 01H, R3 = 04H
LDE	R0,#01H[RR2]	; R0 ← contents of external data memory location 0105H ; (01H + RR2), R0 = 7DH, R2 = 01H, R3 = 04H
LDC (note)	#01H[RR2],R0	; 11H (contents of R0) is loaded into program memory location ; 0105H (01H + 0104H)
LDE	#01H[RR2],R0	; 11H (contents of R0) is loaded into external data memory ; location 0105H (01H + 0104H)
LDC	R0,#1000H[RR2]	; R0 ← contents of program memory location 1104H ; (1000H + 0104H), R0 = 88H, R2 = 01H, R3 = 04H
LDE	R0,#1000H[RR2]	; R0 ← contents of external data memory location 1104H ; (1000H + 0104H), R0 = 98H, R2 = 01H, R3 = 04H
LDC	R0,1104H	; R0 ← contents of program memory location 1104H, R0 = 88H
LDE	R0,1104H	; R0 ← contents of external data memory location 1104H, ; R0 = 98H
LDC (note)	1105H,R0	; 11H (contents of R0) is loaded into program memory location ; 1105H, (1105H) ← 11H
LDE	1105H,R0	; 11H (contents of R0) is loaded into external data memory ; location 1105H, (1105H) ← 11H

NOTE: These instructions are not supported by masked ROM type devices.

LDCD/LDED — Load Memory and Decrement

LDCD/LDED dst,src

Operation: dst ← src
 rr ← rr – 1

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then decremented. The contents of the source are unaffected.

LDCD references program memory and LDED references external data memory. The assembler makes 'lrr' an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst src	2	10	E2	r lrr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory location 1033H = 0CDH, and external data memory location 1033H = 0DDH:

LDCD R8,@RR6 ; 0CDH (contents of program memory location 1033H) is loaded
 ; into R8 and RR6 is decremented by one
 ; R8 = 0CDH, R6 = 10H, R7 = 32H (RR6 ← RR6 – 1)

LDED R8,@RR6 ; 0DDH (contents of data memory location 1033H) is loaded
 ; into R8 and RR6 is decremented by one (RR6 ← RR6 – 1)
 ; R8 = 0DDH, R6 = 10H, R7 = 32H

LDCI/LDEI — Load Memory and Increment

LDCI/LDEI dst,src

Operation: $\text{dst} \leftarrow \text{src}$
 $\text{rr} \leftarrow \text{rr} + 1$

These instructions are used for user stacks or block transfers of data from program or data memory to the register file. The address of the memory location is specified by a working register pair. The contents of the source location are loaded into the destination location. The memory address is then incremented automatically. The contents of the source are unaffected.

LDCI refers to program memory and LDEI refers to external data memory. The assembler makes 'lrr' even for program memory and odd for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
<div style="border: 1px solid black; display: inline-block; padding: 2px 5px;">opc dst src</div>		2	10	E3	r lrr

Examples: Given: R6 = 10H, R7 = 33H, R8 = 12H, program memory locations 1033H = 0CDH and 1034H = 0C5H; external data memory locations 1033H = 0DDH and 1034H = 0D5H:

LDCI R8,@RR6 ; 0CDH (contents of program memory location 1033H) is loaded
 ; into R8 and RR6 is incremented by one ($\text{RR6} \leftarrow \text{RR6} + 1$)
 ; R8 = 0CDH, R6 = 10H, R7 = 34H

LDEI R8,@RR6 ; 0DDH (contents of data memory location 1033H) is loaded
 ; into R8 and RR6 is incremented by one ($\text{RR6} \leftarrow \text{RR6} + 1$)
 ; R8 = 0DDH, R6 = 10H, R7 = 34H

LDCPD/LDEPD — Load Memory with Pre-Decrement

LDCPD/
LDEPD dst,src

Operation: rr ← rr – 1
 dst ← src

These instructions are used for block transfers of data from program or data memory from the register file. The address of the memory location is specified by a working register pair and is first decremented. The contents of the source location are then loaded into the destination location. The contents of the source are unaffected.

LDCPD refers to program memory and LDEPD refers to external data memory. The assembler makes 'lrr' an even number for program memory and an odd number for external data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
opc	src dst	2	14	F2	lrr	r

Examples: Given: R0 = 77H, R6 = 30H, and R7 = 00H:

LDCPD @RR6,R0 ; (RR6 ← RR6 – 1)
 ; 77H (contents of R0) is loaded into program memory location
 ; 2FFFH (3000H – 1H)
 ; R0 = 77H, R6 = 2FH, R7 = 0FFH

LDEPD @RR6,R0 ; (RR6 ← RR6 – 1)
 ; 77H (contents of R0) is loaded into external data memory
 ; location 2FFFH (3000H – 1H)
 ; R0 = 77H, R6 = 2FH, R7 = 0FFH

LDCPI/LDEPI — Load Memory with Pre-Increment

**LDCPI/
LDEPI** dst,src

Operation: $rr \leftarrow rr + 1$
 $dst \leftarrow src$

These instructions are used for block transfers of data from program or data memory from the register file. The address of the memory location is specified by a working register pair and is first incremented. The contents of the source location are loaded into the destination location. The contents of the source are unaffected.

LDCPI refers to program memory and LDEPI refers to external data memory. The assembler makes 'lrr' an even number for program memory and an odd number for data memory.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src dst	2	14	F3	lrr r

Examples: Given: R0 = 7FH, R6 = 21H, and R7 = 0FFH:

LDCPI @RR6,R0 ; (RR6 \leftarrow RR6 + 1)
 ; 7FH (contents of R0) is loaded into program memory
 ; location 2200H (21FFH + 1H)
 ; R0 = 7FH, R6 = 22H, R7 = 00H

LDEPI @RR6,R0 ; (RR6 \leftarrow RR6 + 1)
 ; 7FH (contents of R0) is loaded into external data memory
 ; location 2200H (21FFH + 1H)
 ; R0 = 7FH, R6 = 22H, R7 = 00H

LDW — Load Word

LDW dst,src

Operation: $\text{dst} \leftarrow \text{src}$

The contents of the source (a word) are loaded into the destination. The contents of the source are unaffected.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>	<u>src</u>
opc	src	dst	3	8	C4	RR	RR
				8	C5	RR	IR
opc	dst	src	4	8	C6	RR	IML

Examples: Given: R4 = 06H, R5 = 1CH, R6 = 05H, R7 = 02H, register 00H = 1AH, register 01H = 02H, register 02H = 03H, and register 03H = 0FH:

LDW RR6,RR4 → R6 = 06H, R7 = 1CH, R4 = 06H, R5 = 1CH

LDW 00H,02H → Register 00H = 03H, register 01H = 0FH,
register 02H = 03H, register 03H = 0FH

LDW RR2,@R7 → R2 = 03H, R3 = 0FH,

LDW 04H,@01H → Register 04H = 03H, register 05H = 0FH

LDW RR6,#1234H → R6 = 12H, R7 = 34H

LDW 02H,#0FEDH → Register 02H = 0FH, register 03H = 0EDH

In the second example, please note that the statement "LDW 00H,02H" loads the contents of the source word 02H, 03H into the destination word 00H, 01H. This leaves the value 03H in general register 00H and the value 0FH in register 01H.

The other examples show how to use the LDW instruction with various addressing modes and formats.

MULT — Multiply (Unsigned)

MULT dst,src

Operation: $\text{dst} \leftarrow \text{dst} \times \text{src}$

The 8-bit destination operand (even register of the register pair) is multiplied by the source operand (8 bits) and the product (16 bits) is stored in the register pair specified by the destination address. Both operands are treated as unsigned integers.

Flags: **C:** Set if result is > 255 ; cleared otherwise.
Z: Set if the result is "0"; cleared otherwise.
S: Set if MSB of the result is a "1"; cleared otherwise.
V: Cleared.
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src	dst	3	22	84	RR R
				22	85	RR IR
				22	86	RR IM

Examples: Given: Register 00H = 20H, register 01H = 03H, register 02H = 09H, register 03H = 06H:

MULT 00H, 02H → Register 00H = 01H, register 01H = 20H, register 02H = 09H

MULT 00H, @01H → Register 00H = 00H, register 01H = 0C0H

MULT 00H, #30H → Register 00H = 06H, register 01H = 00H

In the first example, the statement "MULT 00H,02H" multiplies the 8-bit destination operand (in the register 00H of the register pair 00H, 01H) by the source register 02H operand (09H). The 16-bit product, 0120H, is stored in the register pair 00H, 01H.

NEXT — Next

NEXT

Operation: $PC \leftarrow @ IP$
 $IP \leftarrow IP + 2$

The NEXT instruction is useful when implementing threaded-code languages. The program memory word that is pointed to by the instruction pointer is loaded into the program counter. The instruction pointer is then incremented by two.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	10	0F

Example: The following diagram shows one example of how to use the NEXT instruction.

NOP — No Operation

NOP

Operation: No action is performed when the CPU executes this instruction. Typically, one or more NOPs are executed in sequence in order to effect a timing delay of variable duration.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	FF

Example: When the instruction
NOP
is encountered in a program, no operation occurs. Instead, there is a delay in instruction execution time.

OR — Logical OR

OR dst,src

Operation: $\text{dst} \leftarrow \text{dst OR src}$

The source operand is logically ORed with the destination operand and the result is stored in the destination. The contents of the source are unaffected. The OR operation results in a "1" being stored whenever either of the corresponding bits in the two operands is a "1"; otherwise a "0" is stored.

Flags: **C:** Unaffected.
Z: Set if the result is "0"; cleared otherwise.
S: Set if the result bit 7 is set; cleared otherwise.
V: Always cleared to "0".
D: Unaffected.
H: Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div>opc</div> <div>dst src</div>			2	4	42	r	r
				6	43	r	lr
<div>opc</div> <div>src</div> <div>dst</div>			3	6	44	R	R
				6	45	R	IR
<div>opc</div> <div>dst</div> <div>src</div>			3	6	46	R	IM

Examples: Given: R0 = 15H, R1 = 2AH, R2 = 01H, register 00H = 08H, register 01H = 37H, and register 08H = 8AH:

OR R0,R1 → R0 = 3FH, R1 = 2AH
OR R0,@R2 → R0 = 37H, R2 = 01H, register 01H = 37H
OR 00H,01H → Register 00H = 3FH, register 01H = 37H
OR 01H,@00H → Register 00H = 08H, register 01H = 0BFH
OR 00H,#02H → Register 00H = 0AH

In the first example, if working register R0 contains the value 15H and register R1 the value 2AH, the statement "OR R0,R1" logical-ORs the R0 and R1 register contents and stores the result (3FH) in destination register R0.

The other examples show the use of the logical OR instruction with the various addressing modes and formats.

POP — Pop From Stack

POP dst

Operation: dst \leftarrow @SP

SP \leftarrow SP + 1

The contents of the location addressed by the stack pointer are loaded into the destination. The stack pointer is then incremented by one.

Flags: No flags affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	8	50	R
			8	51	IR

Examples: Given: Register 00H = 01H, register 01H = 1BH, SPH (0D8H) = 00H, SPL (0D9H) = 0FBH, and stack register 0FBH = 55H:

POP 00H \rightarrow Register 00H = 55H, SP = 00FCH

POP @00H \rightarrow Register 00H = 01H, register 01H = 55H, SP = 00FCH

In the first example, general register 00H contains the value 01H. The statement "POP 00H" loads the contents of location 00FBH (55H) into destination register 00H and then increments the stack pointer by one. Register 00H then contains the value 55H and the SP points to location 00FCH.

POPUD — Pop User Stack (Decrementing)

POPUD dst,src

Operation: dst ← src
 IR ← IR – 1

This instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then decremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src	dst	3	8	92	R IR

Example: Given: Register 00H = 42H (user stack pointer register), register 42H = 6FH, and register 02H = 70H:

POPUD 02H,@00H → Register 00H = 41H, register 02H = 6FH, register 42H = 6FH

If general register 00H contains the value 42H and register 42H the value 6FH, the statement "POPUD 02H,@00H" loads the contents of register 42H into the destination register 02H. The user stack pointer is then decremented by one, leaving the value 41H.

POPUI — Pop User Stack (Incrementing)

POPUI dst,src

Operation: $\text{dst} \leftarrow \text{src}$
 $\text{IR} \leftarrow \text{IR} + 1$

The POPUI instruction is used for user-defined stacks in the register file. The contents of the register file location addressed by the user stack pointer are loaded into the destination. The user stack pointer is then incremented.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	src	dst	3	8	93	R IR

Example: Given: Register 00H = 01H and register 01H = 70H:

POPUI 02H,@00H → Register 00H = 02H, register 01H = 70H, register 02H = 70H

If general register 00H contains the value 01H and register 01H the value 70H, the statement "POPUI 02H,@00H" loads the value 70H into the destination general register 02H. The user stack pointer (register 00H) is then incremented by one, changing its value from 01H to 02H.

PUSH src

A PUSH instruction decrements the stack pointer value and loads the contents of the source (src) into the location addressed by the decremented stack pointer. The operation then adds the new value to the top of the stack.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
<div>opc</div> <div>src</div>		2	8 (internal clock)	70	R
			8 (external clock)		
			8 (internal clock)		
			8 (external clock)	71	IR

PUSH 40H → Register 40H = 4FH, stack register 0FFH = 4FH,
SPH = 0FFH, SPL = 0FFH

In the first example, if the stack pointer contains the value 0000H, and general register 40H the value 4FH, the statement "PUSH 40H" decrements the stack pointer from 0000 to 0FFFFH. It then loads the contents of register 40H into location 0FFFFH and adds this new value to the top of the stack.

PUSHUD — Push User Stack (Decrementing)

PUSHUD dst,src

Operation: $IR \leftarrow IR - 1$
 $dst \leftarrow src$

This instruction is used to address user-defined stacks in the register file. PUSHUD decrements the user stack pointer and loads the contents of the source into the register addressed by the decremented stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst	src	3	8	82	IR R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 02H = 1AH:

 PUSHUD @00H,01H → Register 00H = 02H, register 01H = 05H, register 02H = 05H

 If the user stack pointer (register 00H, for example) contains the value 03H, the statement "PUSHUD @00H,01H" decrements the user stack pointer by one, leaving the value 02H. The 01H register value, 05H, is then loaded into the register addressed by the decremented user stack pointer.

PUSHUI — Push User Stack (Incrementing)

PUSHUI dst,src

Operation: $IR \leftarrow IR + 1$
 $dst \leftarrow src$

This instruction is used for user-defined stacks in the register file. PUSHUI increments the user stack pointer and then loads the contents of the source into the register location addressed by the incremented user stack pointer.

Flags: No flags are affected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc	dst	src	3	8	83	IR R

Example: Given: Register 00H = 03H, register 01H = 05H, and register 04H = 2AH:

PUSHUI @00H,01H → Register 00H = 04H, register 01H = 05H, register 04H = 05H

If the user stack pointer (register 00H, for example) contains the value 03H, the statement "PUSHUI @00H,01H" increments the user stack pointer by one, leaving the value 04H. The 01H register value, 05H, is then loaded into the location addressed by the incremented user stack pointer.

RCF — Reset Carry Flag

RCF RCF

Operation: $C \leftarrow 0$
The carry flag is cleared to logic zero, regardless of its previous value.

Flags: **C:** Cleared to "0".

No other flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	CF

Example: Given: C = "1" or "0":

The instruction RCF clears the carry flag (C) to logic zero.

RET — Return

RET

Operation: $PC \leftarrow @SP$
 $SP \leftarrow SP + 2$

The RET instruction is normally used to return to the previously executing procedure at the end of a procedure entered by a CALL instruction. The contents of the location addressed by the stack pointer are popped into the program counter. The next statement that is executed is the one that is addressed by the new program counter value.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	8 (internal stack) 10 (internal stack)	AF

Example: Given: $SP = 00FCH$, $(SP) = 101AH$, and $PC = 1234$:

RET \rightarrow $PC = 101AH$, $SP = 00FEH$

The statement "RET" pops the contents of stack pointer location 00FCH (10H) into the high byte of the program counter. The stack pointer then pops the value in location 00FEH (1AH) into the PC's low byte and the instruction at location 101AH is executed. The stack pointer now points to memory location 00FEH.

RL — Rotate Left

RL dst

Operation: $C \leftarrow \text{dst}(7)$

$\text{dst}(0) \leftarrow \text{dst}(7)$

$\text{dst}(n + 1) \leftarrow \text{dst}(n), n = 0-6$

The contents of the destination operand are rotated left one bit position. The initial value of bit 7 is moved to the bit zero (LSB) position and also replaces the carry flag.

Flags: **C:** Set if the bit rotated from the most significant bit position (bit 7) was "1".

Z: Set if the result is "0"; cleared otherwise.

S: Set if the result bit 7 is set; cleared otherwise.

V: Set if arithmetic overflow occurred; cleared otherwise.

D: Unaffected.

H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	90	R
			4	91	IR

Examples: Given: Register 00H = 0AAH, register 01H = 02H and register 02H = 17H:

RL 00H → Register 00H = 55H, C = "1"

RL @01H → Register 01H = 02H, register 02H = 2EH, C = "0"

In the first example, if general register 00H contains the value 0AAH (10101010B), the statement "RL 00H" rotates the 0AAH value left one bit position, leaving the new value 55H (01010101B) and setting the carry and overflow flags.

RLC — Rotate Left Through Carry

RLC dst

Operation: dst (0) ← C
 C ← dst (7)
 dst (n + 1) ← dst (n), n = 0–6

The contents of the destination operand with the carry flag are rotated left one bit position. The initial value of bit 7 replaces the carry flag (C); the initial value of the carry flag replaces bit zero.

Flags: **C:** Set if the bit rotated from the most significant bit position (bit 7) was "1".
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result bit 7 is set; cleared otherwise.
 V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>		
<table border="1"><tr><td>opc</td><td>dst</td></tr></table>	opc	dst		2	4	10	R
	opc	dst					
			4	11	IR		

Examples: Given: Register 00H = 0AAH, register 01H = 02H, and register 02H = 17H, C = "0":

RLC 00H → Register 00H = 54H, C = "1"
RLC @01H → Register 01H = 02H, register 02H = 2EH, C = "0"

In the first example, if general register 00H has the value 0AAH (10101010B), the statement "RLC 00H" rotates 0AAH one bit position to the left. The initial value of bit 7 sets the carry flag and the initial value of the C flag replaces bit zero of register 00H, leaving the value 55H (01010101B). The MSB of register 00H resets the carry flag to "1" and sets the overflow flag.

RR — Rotate Right

RR dst

Operation: $C \leftarrow \text{dst}(0)$
 $\text{dst}(7) \leftarrow \text{dst}(0)$
 $\text{dst}(n) \leftarrow \text{dst}(n + 1), n = 0-6$
The contents of the destination operand are rotated right one bit position. The initial value of bit zero (LSB) is moved to bit 7 (MSB) and also replaces the carry flag (C).

Flags: **C:** Set if the bit rotated from the least significant bit position (bit zero) was "1".
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result bit 7 is set; cleared otherwise.
 V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>	
<table border="1"><tr><td>opc</td><td>dst</td></tr></table>	opc	dst	2	4	E0	R
	opc	dst				
4	E1	IR				

Examples: Given: Register 00H = 31H, register 01H = 02H, and register 02H = 17H:

RR 00H → Register 00H = 98H, C = "1"

RR @01H → Register 01H = 02H, register 02H = 8BH, C = "1"

In the first example, if general register 00H contains the value 31H (00110001B), the statement "RR 00H" rotates this value one bit position to the right. The initial value of bit zero is moved to bit 7, leaving the new value 98H (10011000B) in the destination register. The initial bit zero also resets the C flag to "1" and the sign flag and overflow flag are also set to "1".

RRC — Rotate Right Through Carry

RRC dst

Operation: dst (7) ← C
 C ← dst (0)
 dst (n) ← dst (n + 1), n = 0–6

The contents of the destination operand and the carry flag are rotated right one bit position. The initial value of bit zero (LSB) replaces the carry flag; the initial value of the carry flag replaces bit 7 (MSB).

Flags: **C:** Set if the bit rotated from the least significant bit position (bit zero) was "1".
 Z: Set if the result is "0" cleared otherwise.
 S: Set if the result bit 7 is set; cleared otherwise.
 V: Set if arithmetic overflow occurred, that is, if the sign of the destination changed during rotation; cleared otherwise.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>		
<table border="1"><tr><td>opc</td><td>dst</td></tr></table>	opc	dst		2	4	C0	R
	opc	dst					
			4	C1	IR		

Examples: Given: Register 00H = 55H, register 01H = 02H, register 02H = 17H, and C = "0":

RRC 00H → Register 00H = 2AH, C = "1"
RRC @01H → Register 01H = 02H, register 02H = 0BH, C = "1"

In the first example, if general register 00H contains the value 55H (01010101B), the statement "RRC 00H" rotates this value one bit position to the right. The initial value of bit zero ("1") replaces the carry flag and the initial value of the C flag ("1") replaces bit 7. This leaves the new value 2AH (00101010B) in destination register 00H. The sign flag and overflow flag are both cleared to "0".

SB0 — Select Bank 0

SB0

Operation: BANK ← 0

The SB0 instruction clears the bank address flag in the FLAGS register (FLAGS.0) to logic zero, selecting bank 0 register addressing in the set 1 area of the register file.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	4F

Example: The statement

 SB0

 clears FLAGS.0 to "0", selecting bank 0 register addressing.

SB1 — Select Bank 1

SB1

Operation: BANK \leftarrow 1

The SB1 instruction sets the bank address flag in the FLAGS register (FLAGS.0) to logic one, selecting bank 1 register addressing in the set 1 area of the register file. (Bank 1 is not implemented in some S3C8-series microcontrollers.)

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4	5F

Example: The statement
SB1

sets FLAGS.0 to "1", selecting bank 1 register addressing, if implemented.

SBC — Subtract with Carry

SBC dst,src

Operation: $\text{dst} \leftarrow \text{dst} - \text{src} - \text{c}$

The source operand, along with the current value of the carry flag, is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's-complement of the source operand to the destination operand. In multiple precision arithmetic, this instruction permits the carry ("borrow") from the subtraction of the low-order operands to be subtracted from the subtraction of high-order operands.

Flags:

- C:** Set if a borrow occurred ($\text{src} > \text{dst}$); cleared otherwise.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result is negative; cleared otherwise.
- V:** Set if arithmetic overflow occurred, that is, if the operands were of opposite sign and the sign of the result is the same as the sign of the source; cleared otherwise.
- D:** Always set to "1".
- H:** Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise, indicating a "borrow".

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
<div>opc dst src</div>	2	4	32	r	r
			33	r	lr
<div>opc src dst</div>	3	6	34	R	R
			35	R	IR
<div>opc dst src</div>	3	6	36	R	IM

Examples: Given: R1 = 10H, R2 = 03H, C = "1", register 01H = 20H, register 02H = 03H, and register 03H = 0AH:

SBC R1,R2 → R1 = 0CH, R2 = 03H

SBC R1,@R2 → R1 = 05H, R2 = 03H, register 03H = 0AH

SBC 01H,02H → Register 01H = 1CH, register 02H = 03H

SBC 01H,@02H → Register 01H = 15H, register 02H = 03H, register 03H = 0AH

SBC 01H,#8AH → Register 01H = 95H; C, S, and V = "1"

In the first example, if working register R1 contains the value 10H and register R2 the value 03H, the statement "SBC R1,R2" subtracts the source value (03H) and the C flag value ("1") from the destination (10H) and then stores the result (0CH) in register R1.

SCF — Set Carry Flag

SCF

Operation: $C \leftarrow 1$
The carry flag (C) is set to logic one, regardless of its previous value.

Flags: **C:** Set to "1".
No other flags are affected.

Format:		Bytes	Cycles	Opcode (Hex)
<div>opc</div>		1	4	DF

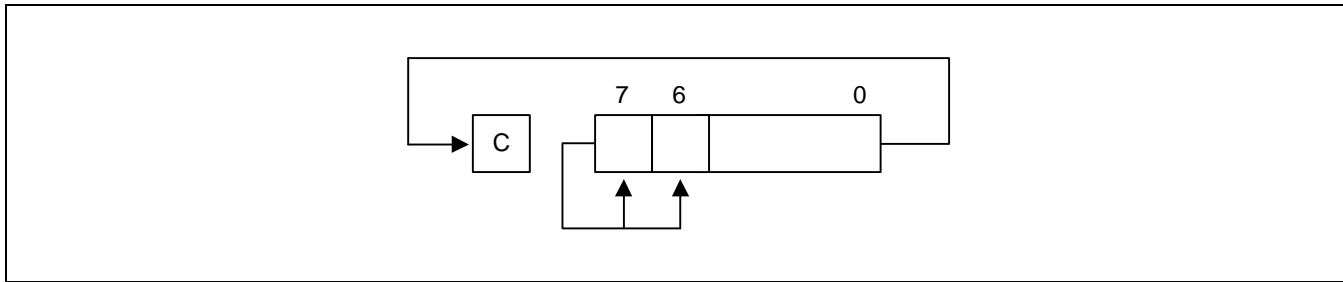

Example: The statement
SCF
sets the carry flag to logic one.

SRA — Shift Right Arithmetic

SRA dst

Operation: dst (7) ← dst (7)
 C ← dst (0)
 dst (n) ← dst (n + 1), n = 0–6

An arithmetic shift-right of one bit position is performed on the destination operand. Bit zero (the LSB) replaces the carry flag. The value of bit 7 (the sign bit) is unchanged and is shifted into bit position 6.

Flags: **C:** Set if the bit shifted from the LSB position (bit zero) was "1".
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result is negative; cleared otherwise.
 V: Always cleared to "0".
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>
opc	dst	2	4	D0	R
			4	D1	IR

Examples: Given: Register 00H = 9AH, register 02H = 03H, register 03H = 0BCH, and C = "1":

SRA 00H → Register 00H = 0CD, C = "0"
SRA @02H → Register 02H = 03H, register 03H = 0DEH, C = "0"

In the first example, if general register 00H contains the value 9AH (10011010B), the statement "SRA 00H" shifts the bit values in register 00H right one bit position. Bit zero ("0") clears the C flag and bit 7 ("1") is then shifted into the bit 6 position (bit 7 remains unchanged). This leaves the value 0CDH (11001101B) in destination register 00H.

SRP/SRP0/SRP1 — Set Register Pointer

SRP src

SRP0 src

SRP1 src

Operation: If src (1) = 1 and src (0) = 0 then: RP0 (3–7) ← src (3–7)
 If src (1) = 0 and src (0) = 1 then: RP1 (3–7) ← src (3–7)
 If src (1) = 0 and src (0) = 0 then: RP0 (4–7) ← src (4–7),
 RP0 (3) ← 0
 RP1 (4–7) ← src (4–7),
 RP1 (3) ← 1

The source data bits one and zero (LSB) determine whether to write one or both of the register pointers, RP0 and RP1. Bits 3–7 of the selected register pointer are written unless both register pointers are selected. RP0.3 is then cleared to logic zero and RP1.3 is set to logic one.

Flags: No flags are affected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>src</u>
opc	src	2	4	31	IM

Examples: The statement

 SRP #40H

 sets register pointer 0 (RP0) at location 0D6H to 40H and register pointer 1 (RP1) at location 0D7H to 48H.

 The statement "SRP0 #50H" sets RP0 to 50H, and the statement "SRP1 #68H" sets RP1 to 68H.

STOP — Stop Operation

STOP

Operation:

The STOP instruction stops both the CPU clock and system clock and causes the microcontroller to enter Stop mode. During Stop mode, the contents of on-chip CPU registers, peripheral registers, and I/O port control and data registers are retained. Stop mode can be released by an external reset operation or by external interrupts. For the reset operation, the RESET pin must be held to Low level until the required oscillation stabilization interval has elapsed.

In application programs, a STOP instruction must be immediately followed by at least three NOP instructions. This ensures an adequate time interval for the clock to stabilize before the next instruction is executed. If three or more NOP instructions are not used after STOP instruction, leakage current could be flown because of the floating state in the internal bus.

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div style="border: 1px solid black; padding: 2px; display: inline-block;">opc</div>	1	4	7F	—	—

Example:

The statement

```

STOP                ; halts all microcontroller operations
NOP
NOP
NOP
  
```

SUB — Subtract

SUB dst,src

Operation: $dst \leftarrow dst - src$

The source operand is subtracted from the destination operand and the result is stored in the destination. The contents of the source are unaffected. Subtraction is performed by adding the two's complement of the source operand to the destination operand.

Flags:

- C:** Set if a "borrow" occurred; cleared otherwise.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result is negative; cleared otherwise.
- V:** Set if arithmetic overflow occurred, that is, if the operands were of opposite signs and the sign of the result is of the same as the sign of the source operand; cleared otherwise.
- D:** Always set to "1".
- H:** Cleared if there is a carry from the most significant bit of the low-order four bits of the result; set otherwise indicating a "borrow".

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>
opc		dst src	2	4	22	r r
				6	23	r lr
opc		src dst	3	6	24	R R
				6	25	R IR
opc		dst src	3	6	26	R IM

Examples: Given: R1 = 12H, R2 = 03H, register 01H = 21H, register 02H = 03H, register 03H = 0AH:

SUB R1,R2 → R1 = 0FH, R2 = 03H
SUB R1,@R2 → R1 = 08H, R2 = 03H
SUB 01H,02H → Register 01H = 1EH, register 02H = 03H
SUB 01H,@02H → Register 01H = 17H, register 02H = 03H
SUB 01H,#90H → Register 01H = 91H; C, S, and V = "1"
SUB 01H,#65H → Register 01H = 0BCH; C and S = "1", V = "0"

In the first example, if working register R1 contains the value 12H and if register R2 contains the value 03H, the statement "SUB R1,R2" subtracts the source value (03H) from the destination value (12H) and stores the result (0FH) in destination register R1.

SWAP — Swap Nibbles

SWAP dst

Operation: dst (0 – 3) ↔ dst (4 – 7)
The contents of the lower four bits and upper four bits of the destination operand are swapped.

Flags: **C:** Undefined.
 Z: Set if the result is "0"; cleared otherwise.
 S: Set if the result bit 7 is set; cleared otherwise.
 V: Undefined.
 D: Unaffected.
 H: Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u>		
<table border="1"><tr><td>opc</td><td>dst</td></tr></table>	opc	dst		2	4	F0	R
	opc	dst					
			4	F1	IR		

Examples: Given: Register 00H = 3EH, register 02H = 03H, and register 03H = 0A4H:

SWAP 00H → Register 00H = 0E3H

SWAP @02H → Register 02H = 03H, register 03H = 4AH

In the first example, if general register 00H contains the value 3EH (00111110B), the statement "SWAP 00H" swaps the lower and upper four bits (nibbles) in the 00H register, leaving the value 0E3H (11100011B).

TCM — Test Complement Under Mask

TCM dst,src

Operation: (NOT dst) AND src

This instruction tests selected bits in the destination operand for a logic one value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask). The TCM statement complements the destination operand, which is then ANDed with the source mask. The zero (Z) flag can then be checked to determine the result. The destination and source operands are unaffected.

Flags:

- C:** Unaffected.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result bit 7 is set; cleared otherwise.
- V:** Always cleared to "0".
- D:** Unaffected.
- H:** Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr Mode <u>dst</u> <u>src</u>	
<table border="1"><tr><td>opc</td><td colspan="2">dst src</td></tr></table>	opc	dst src		2	4	62	r r
	opc	dst src					
6	63	r lr					
<table border="1"><tr><td>opc</td><td>src</td><td>dst</td></tr></table>	opc	src	dst	3	6	64	R R
	opc	src	dst				
6	65	R IR					
<table border="1"><tr><td>opc</td><td>dst</td><td>src</td></tr></table>	opc	dst	src	3	6	66	R IM
opc	dst	src					

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 12H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TCM	R0,R1	→	R0 = 0C7H, R1 = 02H, Z = "1"
TCM	R0,@R1	→	R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"
TCM	00H,01H	→	Register 00H = 2BH, register 01H = 02H, Z = "1"
TCM	00H,@01H	→	Register 00H = 2BH, register 01H = 02H, register 02H = 23H, Z = "1"
TCM	00H,#34	→	Register 00H = 2BH, Z = "0"

In the first example, if working register R0 contains the value 0C7H (11000111B) and register R1 the value 02H (00000010B), the statement "TCM R0,R1" tests bit one in the destination register for a "1" value. Because the mask value corresponds to the test bit, the Z flag is set to logic one and can be tested to determine the result of the TCM operation.

TM — Test Under Mask

TM dst,src

Operation: dst AND src

This instruction tests selected bits in the destination operand for a logic zero value. The bits to be tested are specified by setting a "1" bit in the corresponding position of the source operand (mask), which is ANDed with the destination operand. The zero (Z) flag can then be checked to determine the result. The destination and source operands are unaffected.

Flags:

- C:** Unaffected.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result bit 7 is set; cleared otherwise.
- V:** Always reset to "0".
- D:** Unaffected.
- H:** Unaffected.

Format:

		Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div>opc</div> <div>dst src</div>		2	4	72	r	r
			6	73	r	lr
<div>opc</div> <div>src</div> <div>dst</div>		3	6	74	R	R
			6	75	R	IR
<div>opc</div> <div>dst</div> <div>src</div>		3	6	76	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

TM	R0,R1	→	R0 = 0C7H, R1 = 02H, Z = "0"
TM	R0,@R1	→	R0 = 0C7H, R1 = 02H, register 02H = 23H, Z = "0"
TM	00H,01H	→	Register 00H = 2BH, register 01H = 02H, Z = "0"
TM	00H,@01H	→	Register 00H = 2BH, register 01H = 02H, register 02H = 23H, Z = "0"
TM	00H,#54H	→	Register 00H = 2BH, Z = "1"

In the first example, if working register R0 contains the value 0C7H (11000111B) and register R1 the value 02H (00000010B), the statement "TM R0,R1" tests bit one in the destination register for a "0" value. Because the mask value does not match the test bit, the Z flag is cleared to logic zero and can be tested to determine the result of the TM operation.

WFI — Wait for Interrupt

WFI

Operation:

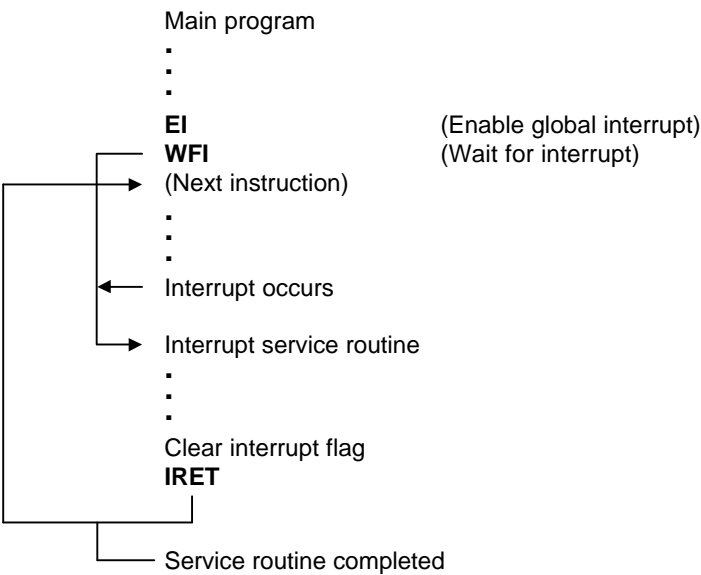

The CPU is effectively halted until an interrupt occurs, except that DMA transfers can still take place during this wait state. The WFI status can be released by an internal interrupt, including a fast interrupt .

Flags: No flags are affected.

Format:

	Bytes	Cycles	Opcode (Hex)
<div>opc</div>	1	4n	3F
		(n = 1, 2, 3, ...)	

Example: The following sample program structure shows the sequence of operations that follow a "WFI" statement:

XOR — Logical Exclusive OR

XOR dst,src

Operation: $\text{dst} \leftarrow \text{dst XOR src}$

The source operand is logically exclusive-ORed with the destination operand and the result is stored in the destination. The exclusive-OR operation results in a "1" bit being stored whenever the corresponding bits in the operands are different; otherwise, a "0" bit is stored.

Flags:

- C:** Unaffected.
- Z:** Set if the result is "0"; cleared otherwise.
- S:** Set if the result bit 7 is set; cleared otherwise.
- V:** Always reset to "0".
- D:** Unaffected.
- H:** Unaffected.

Format:

			Bytes	Cycles	Opcode (Hex)	Addr <u>dst</u>	Mode <u>src</u>
<div> <div>opc</div> <div>dst src</div> </div>			2	4	B2	r	r
				6	B3	r	lr
<div> <div>opc</div> <div>src</div> <div>dst</div> </div>			3	6	B4	R	R
				6	B5	R	IR
<div> <div>opc</div> <div>dst</div> <div>src</div> </div>			3	6	B6	R	IM

Examples: Given: R0 = 0C7H, R1 = 02H, R2 = 18H, register 00H = 2BH, register 01H = 02H, and register 02H = 23H:

```

XOR    R0,R1      →    R0 = 0C5H, R1 = 02H
XOR    R0,@R1     →    R0 = 0E4H, R1 = 02H, register 02H = 23H
XOR    00H,01H    →    Register 00H = 29H, register 01H = 02H
XOR    00H,@01H   →    Register 00H = 08H, register 01H = 02H, register 02H = 23H
XOR    00H,#54H   →    Register 00H = 7FH
  
```

In the first example, if working register R0 contains the value 0C7H and if register R1 contains the value 02H, the statement "XOR R0,R1" logically exclusive-ORs the R1 value with the R0 value and stores the result (0C5H) in the destination register R0.

NOTES

7

CLOCK CIRCUIT

OVERVIEW

The clock frequency generated for the S3C831B by an external crystal can range from 0.4 MHz to 9.0 MHz. The maximum CPU clock frequency is 9.0 MHz. The X_{IN} and X_{OUT} pins connect the external oscillator or clock source to the on-chip clock circuit.

SYSTEM CLOCK CIRCUIT

The system clock circuit has the following components:

- External crystal or ceramic resonator oscillation source (or an external clock source)
- Oscillator stop and wake-up functions
- Programmable frequency divider for the CPU clock (fxx divided by 1, 2, 8, or 16)
- System clock control register, CLKCON
- STOP control register, STPCON

CPU Clock Notation

In this document, the following notation is used for descriptions of the CPU clock;

fx: main clock

fxt: sub clock (the fxt is not implemented in the S3C831B)

fxx: selected system clock

**Figure 7-1. Main Oscillator Circuit
(Crystal or Ceramic Oscillator)**

**Figure 7-2. Main Oscillator Circuit
(External Oscillator)**

CLOCK STATUS DURING POWER-DOWN MODES

The two power-down modes, Stop mode and Idle mode, affect the system clock as follows:

- In Stop mode, the main oscillator is halted. Stop mode is released, and the oscillator is started, by a reset operation or an external interrupt (with RC delay noise filter).
- In Idle mode, the internal clock signal is gated to the CPU, but not to interrupt structure, timers, timer/counters, and watch timer. Idle mode is released by a reset or by an external or internal interrupt.

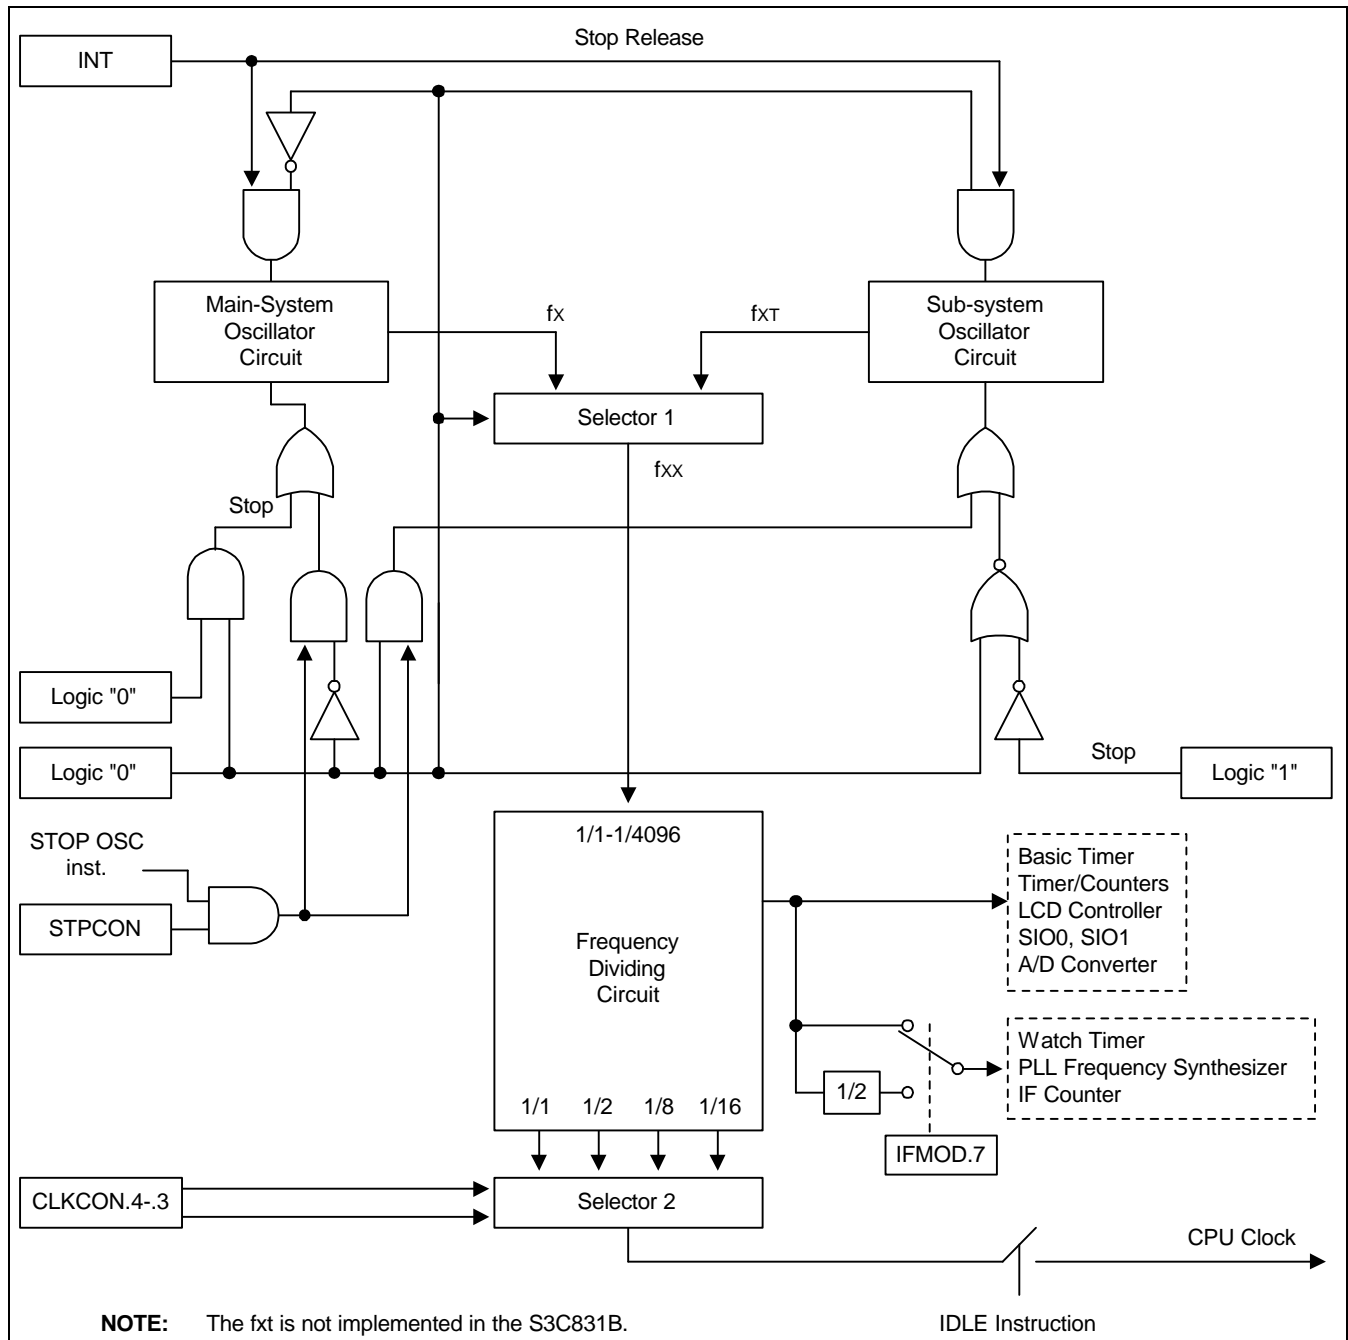

Figure 7-3. System Clock Circuit Diagram

SYSTEM CLOCK CONTROL REGISTER (CLKCON)

The system clock control register, CLKCON, is located in the set 1, address D4H. It is read/write addressable and has the following functions:

- Oscillator frequency divide-by value

After the main oscillator is activated, and the $f_{xx}/16$ (the slowest clock speed) is selected as the CPU clock. If necessary, you can then increase the CPU clock speed $f_{xx}/8$, $f_{xx}/2$, or $f_{xx}/1$.

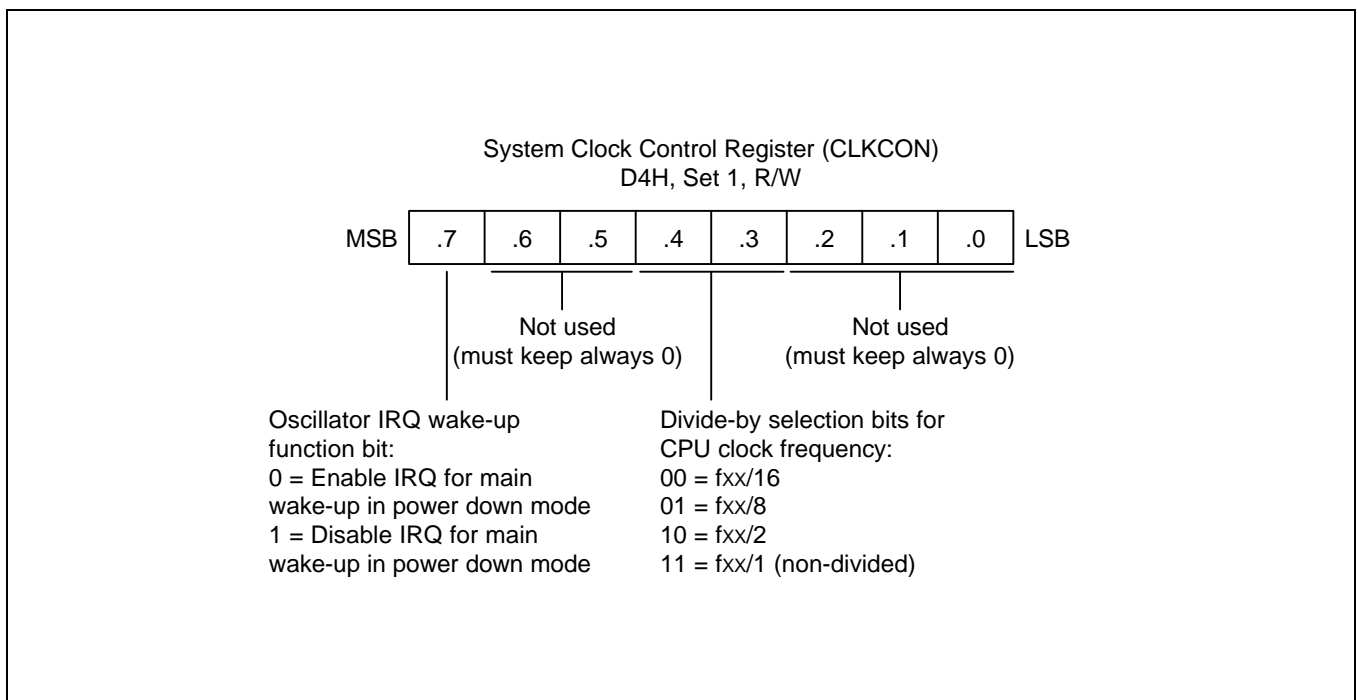

Figure 7-4. System Clock Control Register (CLKCON)

NOTE: Before execute the STOP instruction, set this STPCON register as "10100101B".
Otherwise the STOP instruction will not execute as well as reset will be generated.

Figure 7-5. STOP Control Register (STPCON)

8

RESET and POWER-DOWN

SYSTEM RESET

OVERVIEW

During a power-on reset, the voltage at V_{DD} goes to High level and the RESET pin is forced to Low level. The RESET signal is input through a schmitt trigger circuit where it is then synchronized with the CPU clock. This procedure brings the S3C831B into a known operating status.

To allow time for internal CPU clock oscillation to stabilize, the RESET pin must be held to Low level for a minimum time interval after the power supply comes within tolerance. The minimum required time of a reset operation for oscillation stabilization is 1 millisecond.

Whenever a reset occurs during normal operation (that is, when both V_{DD} and RESET are High level), the RESET pin is forced Low level and the reset operation starts. All system and peripheral control registers are then reset to their default hardware values

In summary, the following sequence of events occurs during a reset operation:

- All interrupt is disabled.
- The watchdog function (basic timer) is enabled.
- Ports 0-3 are set to input mode, and all pull-up resistors are disabled for the I/O port.
- Peripheral control and data register settings are disabled and reset to their default hardware values.
- The program counter (PC) is loaded with the program reset address in the ROM, 0100H.
- When the programmed oscillation stabilization time interval has elapsed, the instruction stored in ROM location 0100H (and 0101H) is fetched and executed.

NORMAL MODE RESET OPERATION

In normal (masked ROM) mode, the Test pin is tied to V_{SS} . A reset enables access to the 64-Kbyte on-chip ROM.

NOTE

To program the duration of the oscillation stabilization interval, you make the appropriate settings to the basic timer control register, BTCON, *before* entering Stop mode. Also, if you do not want to use the basic timer watchdog function (which causes a system reset if a basic timer counter overflow occurs), you can disable it by writing "1010B" to the upper nibble of BTCON.

HARDWARE RESET VALUES

Table 8-1, 8-2, 8-3 list the reset values for CPU and system registers, peripheral control registers, and peripheral data registers following a reset operation. The following notation is used to represent reset values:

- A "1" or a "0" shows the reset bit value as logic one or logic zero, respectively.
- An "x" means that the bit value is undefined after a reset.
- A dash ("–") means that the bit is either not used or not mapped, but read 0 is the bit value.

Table 8-1. S3C831B Set 1 Register and Values after RESET

Register Name	Mnemonic	Address		Bit Values after RESET

POWER-DOWN MODES

STOP MODE

Stop mode is invoked by the instruction STOP (opcode 7FH). In Stop mode, the operation of the CPU and all peripherals is halted. That is, the on-chip main oscillator stops and the supply current is reduced to less than 3 μ A. All system functions stop when the clock “freezes”, but data stored in the internal register file is retained. Stop mode can be released in one of two ways: by a reset or by external interrupts, for more details see Figure 7-3.

NOTE

Do not use stop mode if you are using an external clock source because X_{IN} input must be restricted internally to V_{SS} to reduce current leakage.

Using RESET to Release Stop Mode

Stop mode is released when the RESET signal is released and returns to high level: all system and peripheral control registers are reset to their default hardware values and the contents of all data registers are retained. A reset operation automatically selects a slow clock f_{xx}/16 because CLKCON.3 and CLKCON.4 are cleared to '00B'. After the programmed oscillation stabilization interval has elapsed, the CPU starts the system initialization routine by fetching the program instruction stored in ROM location 0100H.

Using an External Interrupt to Release Stop Mode

External interrupts with an RC-delay noise filter circuit can be used to release Stop mode. Which interrupt you can use to release Stop mode in a given situation depends on the microcontroller's current internal operating mode. The external interrupts in the S3C831B interrupt structure that can be used to release Stop mode are:

- External interrupts P1.0–P1.7 (INT0–INT7)

Please note the following conditions for Stop mode release:

- If you release Stop mode using an external interrupt, the current values in system and peripheral control registers are unchanged except STPCON register.
- If you use an internal or external interrupt for stop mode release, you can also program the duration of the oscillation stabilization interval. To do this, you must make the appropriate control and clock settings *before* entering stop mode.
- When the Stop mode is released by external interrupt, the CLKCON.4 and CLKCON.3 bit-pair setting remains unchanged and the currently selected clock value is used.
- The external interrupt is serviced when the Stop mode release occurs. Following the IRET from the service routine, the instruction immediately following the one that initiated Stop mode is executed.

How to Enter into Stop Mode

Handling STPCON register then writing Stop instruction (keep the order).

```
LD      STPCON, #10100101B
STOP
NOP
NOP
NOP
```

IDLE MODE

Idle mode is invoked by the instruction IDLE (opcode 6FH). In idle mode, CPU operations are halted while some peripherals remain active. During idle mode, the internal clock signal is gated away from the CPU, but all peripherals remain active. Port pins retain the mode (input or output) they had at the time idle mode was entered.

There are two ways to release idle mode:

1. Execute a reset. All system and peripheral control registers are reset to their default values and the contents of all data registers are retained. The reset automatically selects the slow clock fxx/16 because CLKCON.4 and CLKCON.3 are cleared to '00B'. If interrupts are masked, a reset is the only way to release idle mode.
2. Activate any enabled interrupt, causing idle mode to be released. When you use an interrupt to release idle mode, the CLKCON.4 and CLKCON.3 register values remain unchanged, and the currently selected clock value is used. The interrupt is then serviced. When the return-from-interrupt (IRET) occurs, the instruction immediately following the one that initiated idle mode is executed.

9

I/O PORTS

OVERVIEW

The S3C831B microcontroller has four bit-programmable and five nibble-programmable I/O ports, P0–P8. The port 0–8 are all 8-bit ports. This gives a total of 72 I/O pins. Each port can be flexibly configured to meet application design requirements. The CPU accesses ports by directly writing or reading port registers. No special I/O instructions are required. All ports of the S3C831B can be configured to input or output mode and P4–P8 are shared with LCD segment signals.

Table 9-1 gives you a general overview of the S3C831B I/O port functions.

Table 9-1. S3C831B Port Configuration Overview

Port	Configuration Options
0	1-bit programmable I/O port. Schmitt trigger input or push-pull, open-drain output mode selected by software; software assignable pull-up. Alternately P0.1–P0.7 can be used as T0CLK, T0CAP, T0OUT/T0PWM, T1CLK, T1OUT, T2CLK, T2OUT.
1	1-bit programmable I/O port. Input or push-pull output mode selected by software; software assignable pull-up (P1.0–.3: Schmitt trigger input, P1.4–.7: Input). P1.0–P1.7 can be used as inputs for external interrupts INT0–INT7 (with noise filter and interrupt control).
2	1-bit programmable I/O port. Schmitt trigger input or push-pull output mode selected by software; software assignable pull-up. Alternately P2.0–P2.7 can be used as AD0–AD7.
3	1-bit programmable I/O port. Input or push-pull, open-drain output mode selected by software; software assignable pull-up. Alternately P3.0–P3.6 can be used as BUZ, SCK0, SO0, SI0, SCK1, SO1, SI1.
4	4-bit programmable I/O port. Input or push-pull, open-drain output mode selected by software; software assignable pull-up. P4.0–P4.7 can alternately be used as outputs for LCD segment signals.
5	4-bit programmable I/O port. Input or push-pull, open-drain output mode selected by software; software assignable pull-up. P5.0–P5.7 can alternately be used as outputs for LCD segment signals.
6	4-bit programmable I/O port. Schmitt trigger input or push-pull, open-drain output mode selected by software; software assignable pull-up. P6.0–P6.7 can alternately be used as outputs for LCD segment signals.
7	4-bit programmable I/O port. Schmitt trigger input or push-pull, open-drain output mode selected by software; software assignable pull-up. P7.0–P7.7 can alternately be used as outputs for LCD segment signals.
8	4-bit programmable I/O port. Schmitt trigger input or push-pull, open-drain output mode selected by software; software assignable pull-up. P8.0–P8.7 can alternately be used as outputs for LCD segment signals.

PORT DATA REGISTERS

Table 9-2 gives you an overview of the register locations of all nine S3C831B I/O port data registers. Data registers for ports 0, 1, 2, 3, 4, 5, 6, 7 and 8 have the general format shown in Figure 9-1.

Table 9-2. Port Data Register Summary

Register Name	Mnemonic	Decimal	Hex	Location	R/W
Port 0 data register	P0	240	F0H	Set 1, Bank 1	R/W
Port 1 data register	P1	241	F1H	Set 1, Bank 1	R/W
Port 2 data register	P2	242	F2H	Set 1, Bank 1	R/W
Port 3 data register	P3	243	F3H	Set 1, Bank 1	R/W
Port 4 data register	P4	244	F4H	Set 1, Bank 1	R/W
Port 5 data register	P5	245	F5H	Set 1, Bank 1	R/W
Port 6 data register	P6	246	F6H	Set 1, Bank 1	R/W
Port 7 data register	P7	247	F7H	Set 1, Bank 1	R/W
Port 8 data register	P8	248	F8H	Set 1, Bank 1	R/W

PORT 0

Port 0 is an 8-bit I/O port with individually configurable pins. Port 0 pins are accessed directly by writing or reading the port 0 data register, P0 at location F0H in set 1, bank 1. P0.0–P0.7 can serve inputs, as outputs (push pull or open-drain) or you can configure the following alternative functions:

- Low-nibble pins (P0.1-P0.3): T0CLK, T0CAP, T0OUT/T0PWM
- High-nibble pins (P0.4-P0.7): T1CLK, T1OUT, T2CLK, T2OUT

Port 0 Control Register

Port 0 has two 8-bit control registers: P0CONH for P0.4–P0.7 and P0CONL for P0.0–P0.3. A reset clears the P0CONH and P0CONL registers to “00H”, configuring all pins to input mode. You use control registers settings to select input or output mode (push-pull or open drain) and enable the alternative functions.

When programming the port, please remember that any alternative peripheral I/O function you configure using the port 0 control registers must also be enabled in the associated peripheral module.

Port 0 Pull-up Resistor Enable Register (P0PUR)

Using the port 0 pull-up resistor enable register, P0PUR (E2H, set 1, bank 1), you can configure pull-up resistors to individual port 0 pins.

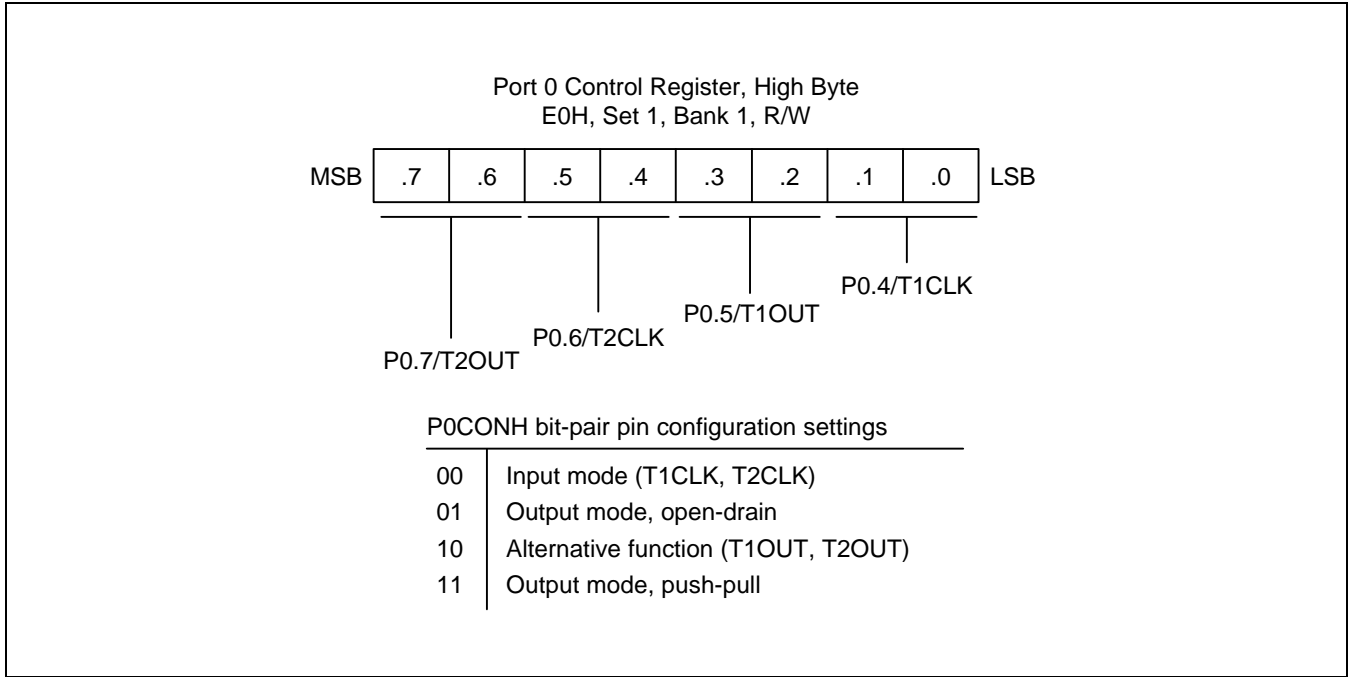

Figure 9-1. Port 0 High-Byte Control Register (P0CONH)

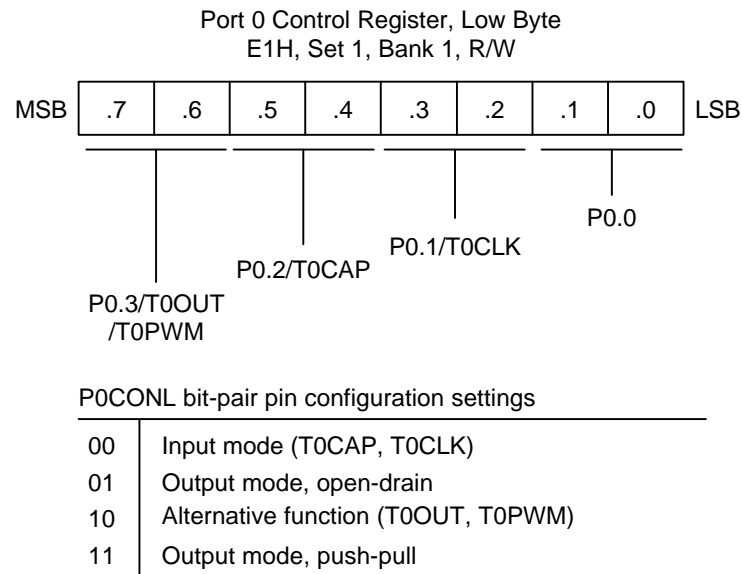

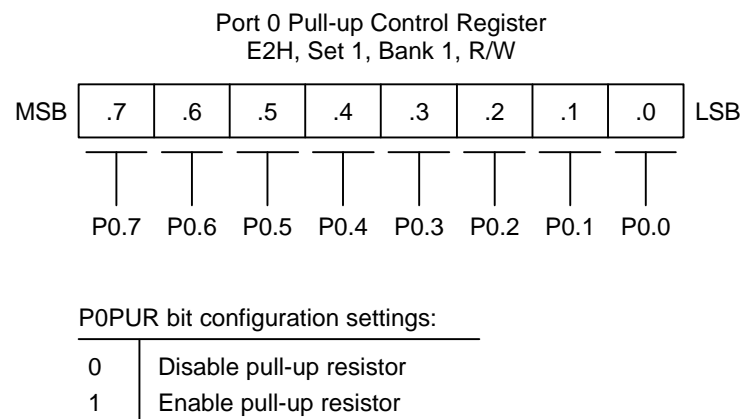

Figure 9-2. Port 0 Low-Byte Control Register (P0CONL)

NOTE: The corresponding pull-up resistor is disabled automatically, when a bit of port 0 is selected as output mode.

Figure 9-3. Port 0 Pull-up Control Register (P0PUR)

PORT 1

Port 1 is an 8-bit I/O Port that you can use two ways:

- General-purpose I/O
- External interrupt inputs for INT0–INT7

Port 1 is accessed directly by writing or reading the port 1 data register, P1 at location F1H in set 1, bank 1.

NOTE

The port 1 inputs can be disabled by PG2CON.5–.4 when the port is selected as input mode. Refer to the PG2CON register.

Port 1 Control Register (P1CONH, P1CONL)

Port 1 pins are configured individually by bit-pair settings in two control registers located in set 1, bank 1: P1CONL (low byte, E5H) and P1CONH (high byte, E4H).

When you select output mode, a push-pull circuit is automatically configured. In input mode, three different selections are available:

- Input with interrupt generation on falling edges (P1.0-.3: Schmitt trigger input).
- Input with interrupt generation on rising edges (P1.0-.3: Schmitt trigger input).
- Input with interrupt generation on falling/rising edges (P1.0-.3: Schmitt trigger input).

Port 1 Interrupt Enable and Pending Registers (P1INT, P1PND)

To process external interrupts at the port 1 pins, two additional control registers are provided: the port 1 interrupt enable register P1INT (E6H, set 1, bank 1) and the port 1 interrupt pending register P1PND (E7H, set 1, bank 1).

The port 1 interrupt pending register P1PND lets you check for interrupt pending conditions and clear the pending condition when the interrupt service routine has been initiated. The application program detects interrupt requests by polling the P1PND register at regular intervals.

When the interrupt enable bit of any port 1 pin is “1”, a rising or falling edge at that pin will generate an interrupt request. The corresponding P1PND bit is then automatically set to “1” and the IRQ level goes low to signal the CPU that an interrupt request is waiting. When the CPU acknowledges the interrupt request, application software must clear the pending condition by writing a “0” to the corresponding P1PND bit.

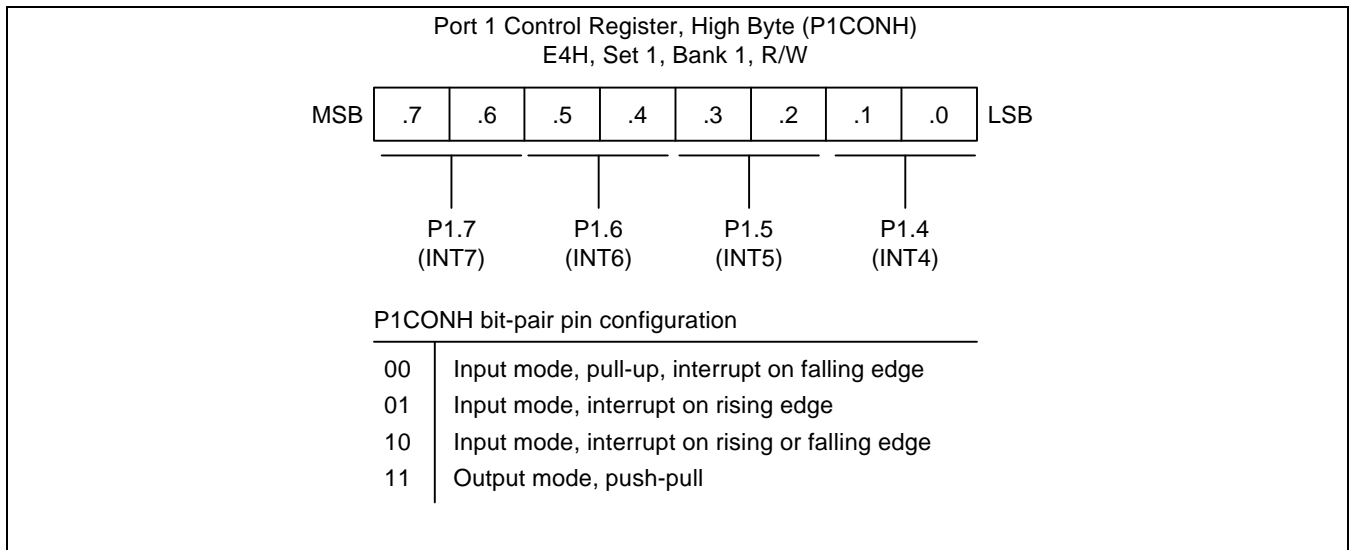

Figure 9-4. Port 1 High-Byte Control Register (P1CONH)

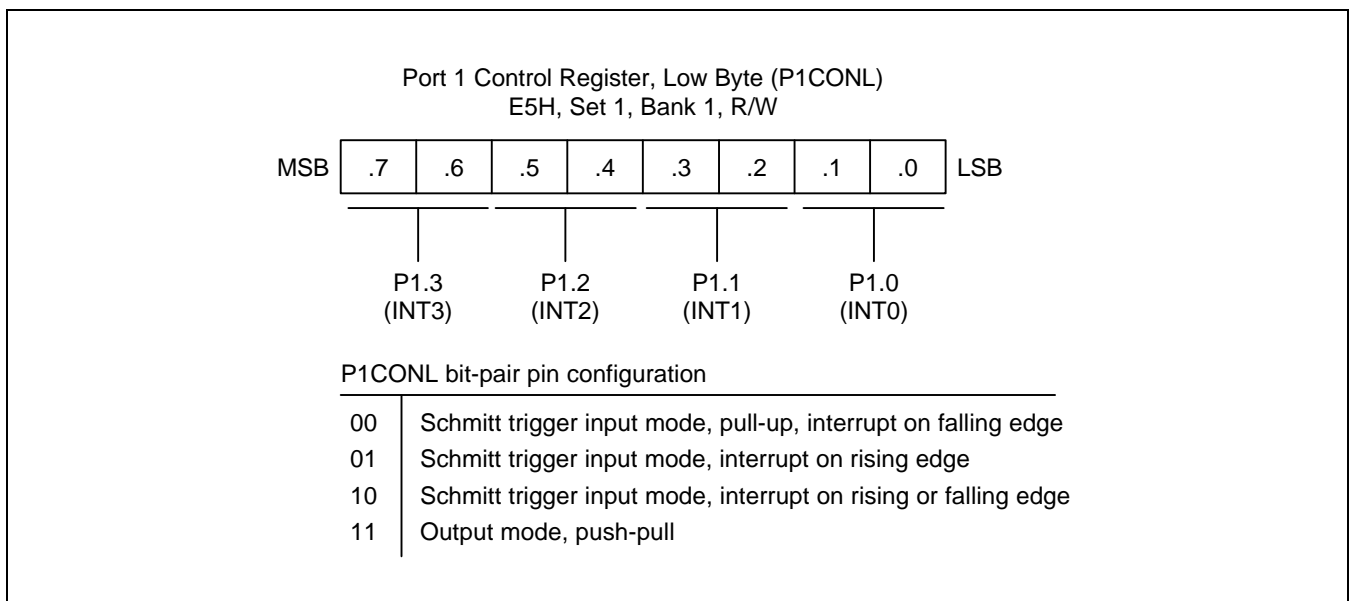

Figure 9-5. Port 1 Low-Byte Control Register (P1CONL)

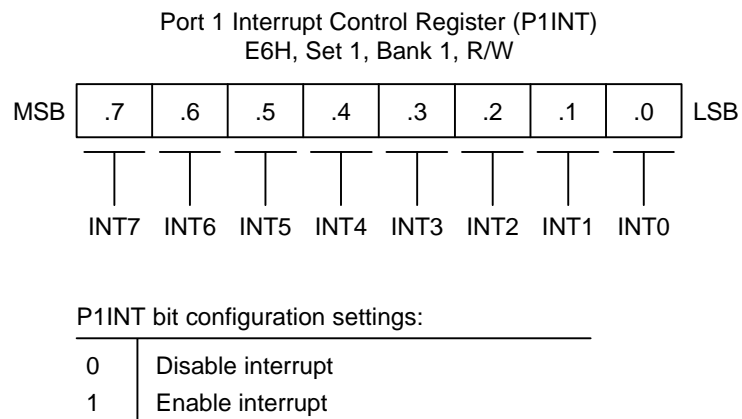

Figure 9-6. Port 1 Interrupt Control Register (P1INT)

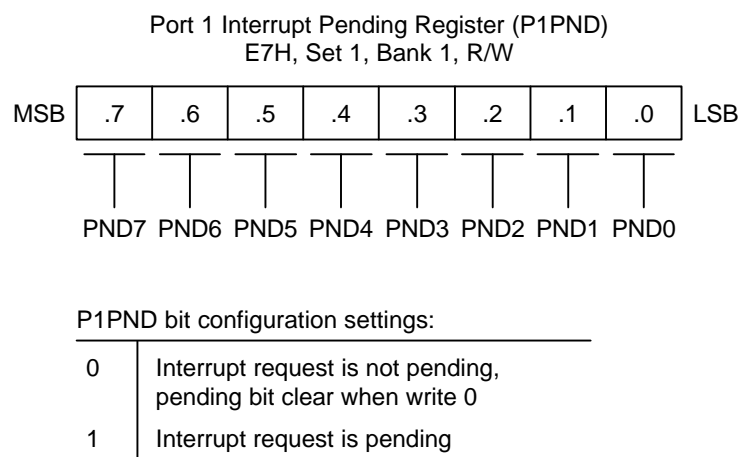

Figure 9-7. Port 1 Interrupt Pending Register (P1PND)

PORT 2

Port 2 is an 8-bit I/O port that can be used for general-purpose I/O as A/D converter inputs, AD0–AD7. The pins are accessed directly by writing or reading the port 2 data register, P2 at location F2H in set 1, bank 1.

To individually configure the port 2 pins P2.0–P2.7, you make bit-pair settings in two control registers located in set 1, bank 1: P2CONL (low byte, E9H) and P2CONH (high byte, E8H). In input mode, ADC voltage input are also available.

Port 2 Control Registers

Two 8-bit control registers are used to configure port 2 pins: P2CONL (E9H, set 1, Bank 1) for pins P2.0–P2.3 and P2CONH (E8H, set 1, Bank 1) for pins P2.4–P2.7. Each byte contains four bit-pairs and each bit-pair configures one port 2 pin. The P2CONH and the P2CONL registers also control the alternative functions.

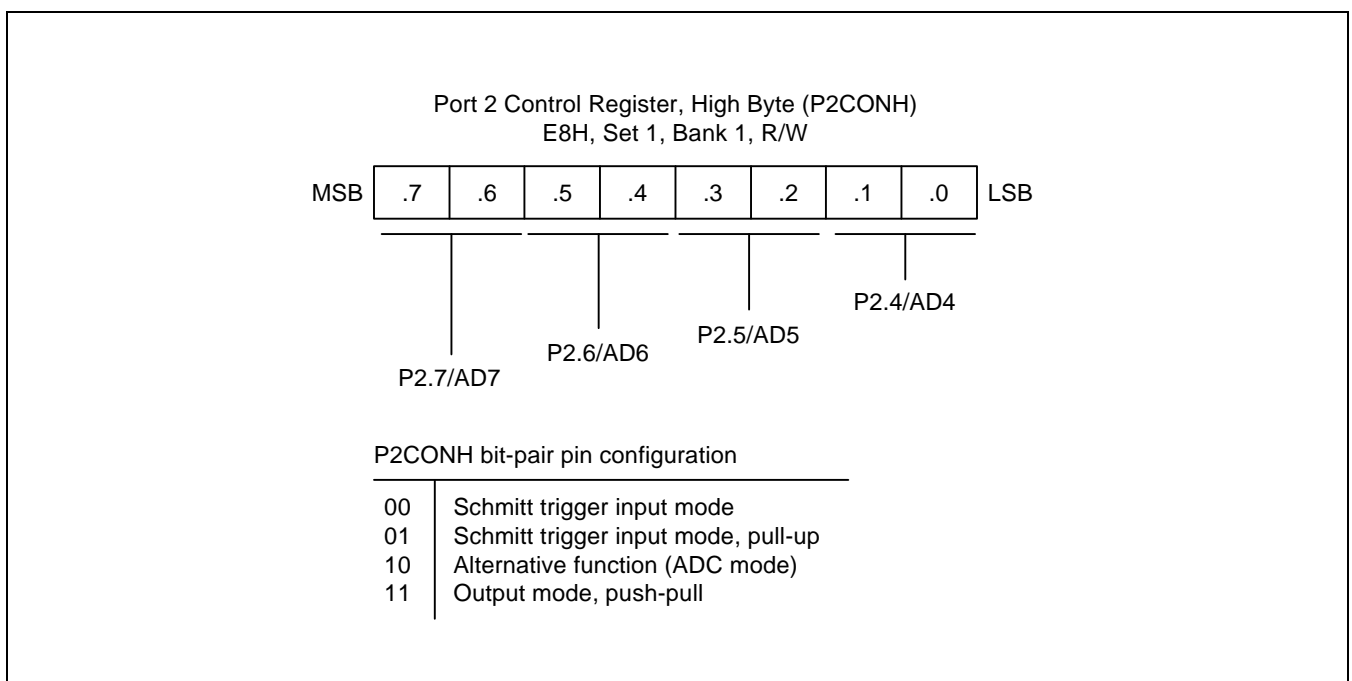

Figure 9-8. Port 2 High-Byte Control Register (P2CONH)

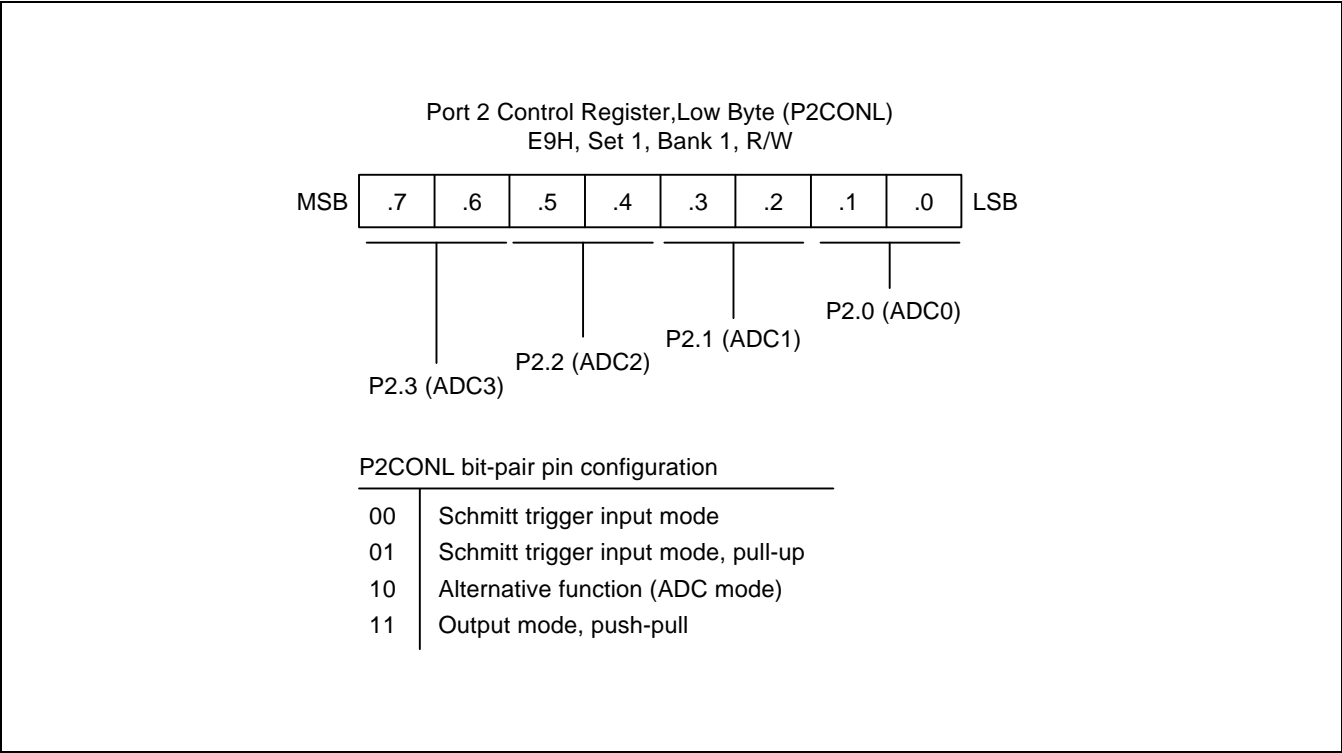

Figure 9-9. Port 2 Low-Byte Control Register (P2CONL)

PORT 3

Port 3 is an 8-bit I/O port with individually configurable pins. Port 3 pins are accessed directly by writing or reading the port 3 data register, P3 at location F3H in set 1, bank 1. P3.0–P3.7 can serve as inputs or as push-pull, open-drain outputs. You can configure the following alternative functions:

— BUZ, SCK0, SO0, SI0, SCK1, SO1, and SI1

Port 3 Control Registers

Port 3 has two 8-bit control registers: P3CONH for P3.4–P3.7 and P3CONL for P3.0–P3.3. A reset clears the P3CONH and P3CONL registers to “00H”, configuring all pins to input mode. You use control registers settings to select input or output mode, enable pull-up resistors, and enable the alternative functions.

When programming this port, please remember that any alternative peripheral I/O function you configure using the port 3 control registers must also be enabled in the associated peripheral module.

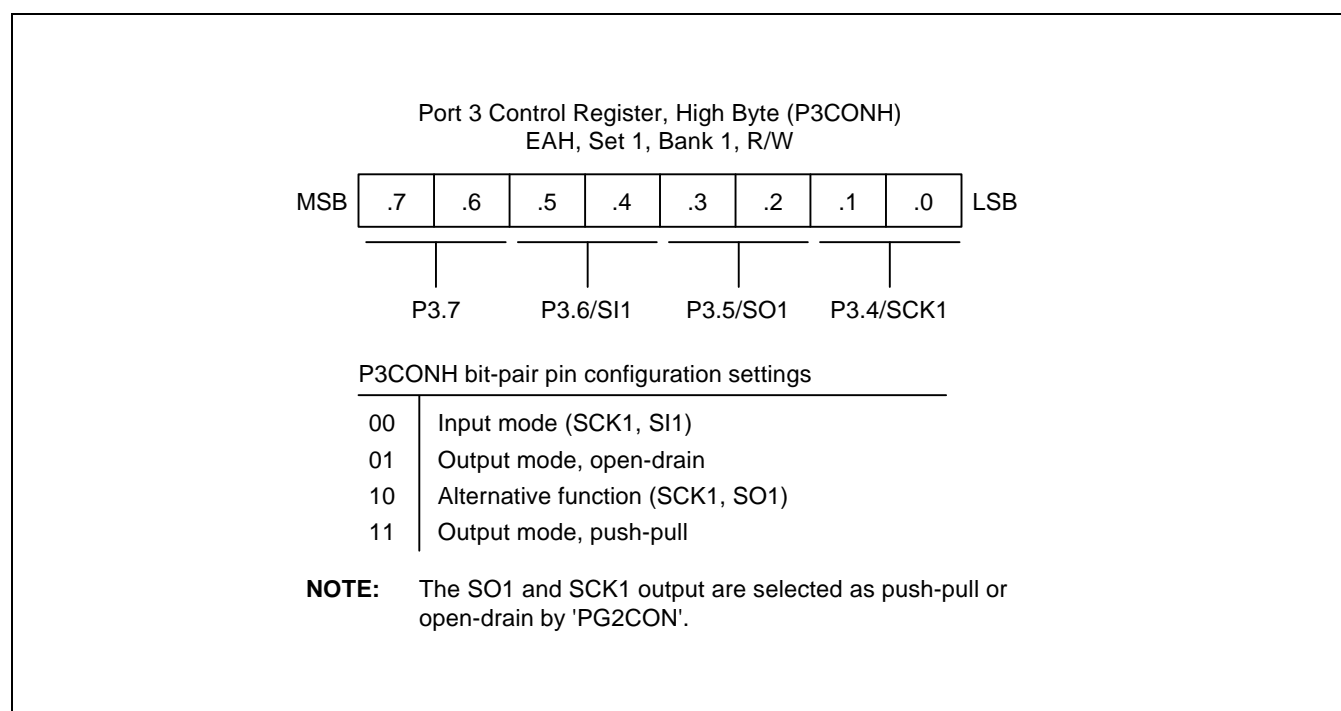

Figure 9-10. Port 3 High-Byte Control Register (P3CONH)

P3CONL bit-pair pin configuration settings

00	Input mode (SCK0, SI0)
01	Output mode, open-drain
10	Alternative function (BUZ, SCK0, SO0)
11	Output mode, push-pull

NOTE: The SO0 and SCK0 output are selected as push-pull or open-drain by 'PG2CON'.

Figure 9-11. Port 3 Low-Byte Control Register (P3CONL)

P3PUR bit configuration settings:

0	Disable pull-up resistor
1	Enable pull-up resistor

NOTE: The corresponding pull-up resistor is disabled automatically, when a bit of port 3 is selected as output mode.

Figure 9-12. Port 3 Pull-up Control Register (P3PUR)

PORT 4, 5

Port 4 and 5 are 8-bit I/O ports with nibble configurable pins, respectively. Port 4 and 5 pins are accessed directly by writing or reading the port 4 and 5 data registers, P4 at location F4H and P5 at location F5H in set 1, bank 1. P4.0–P4.7 and P5.0–P5.7 can serve as inputs (with or without pull-ups), as output (open drain or push-pull). And they can serve as segment pins for LCD, also.

Port Group 0 Control Register

Port 4 and 5 have a 8-bit control register: PG0CON.4–.7 for P4.0–P4.7 and PG0CON.0–.3 for P5.0–P5.7. A reset clears the PG0CON register to “00H”, configuring all pins to input mode.

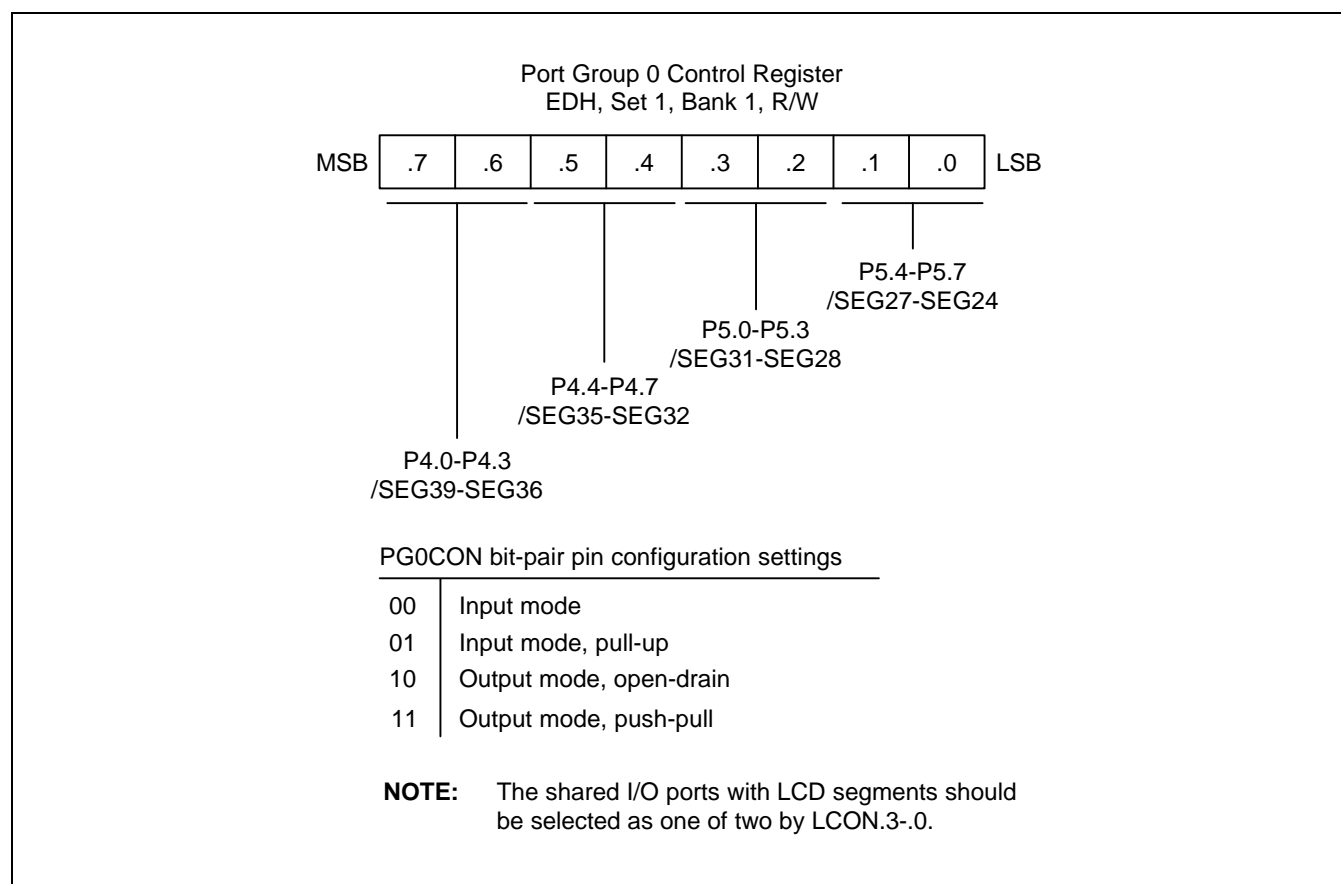

Figure 9-13. Port Group 0 Control Register (PG0CON)

PORT 6, 7

Port 6 and 7 are 8-bit I/O port with nibble configurable pins, respectively. Port 6 and 7 pins are accessed directly by writing or reading the port 6 and 7 data registers, P6 at location F6H and P7 at location F7H in set 1, bank 1. P6.0–P6.7 and P7.0–P7.7 can serve as inputs (with or without pull-ups), as output (open drain or push-pull). And they can serve as segment pins for LCD also.

Port Group 1 Control Register

Port 6 and 7 have a 8-bit control register: PG1CON.4–.7 for P6.0–P6.7 and PG1CON.0–.3 for P7.0–P7.7. A reset clears the PG1CON register to “00H”, configuring all pins to input mode.

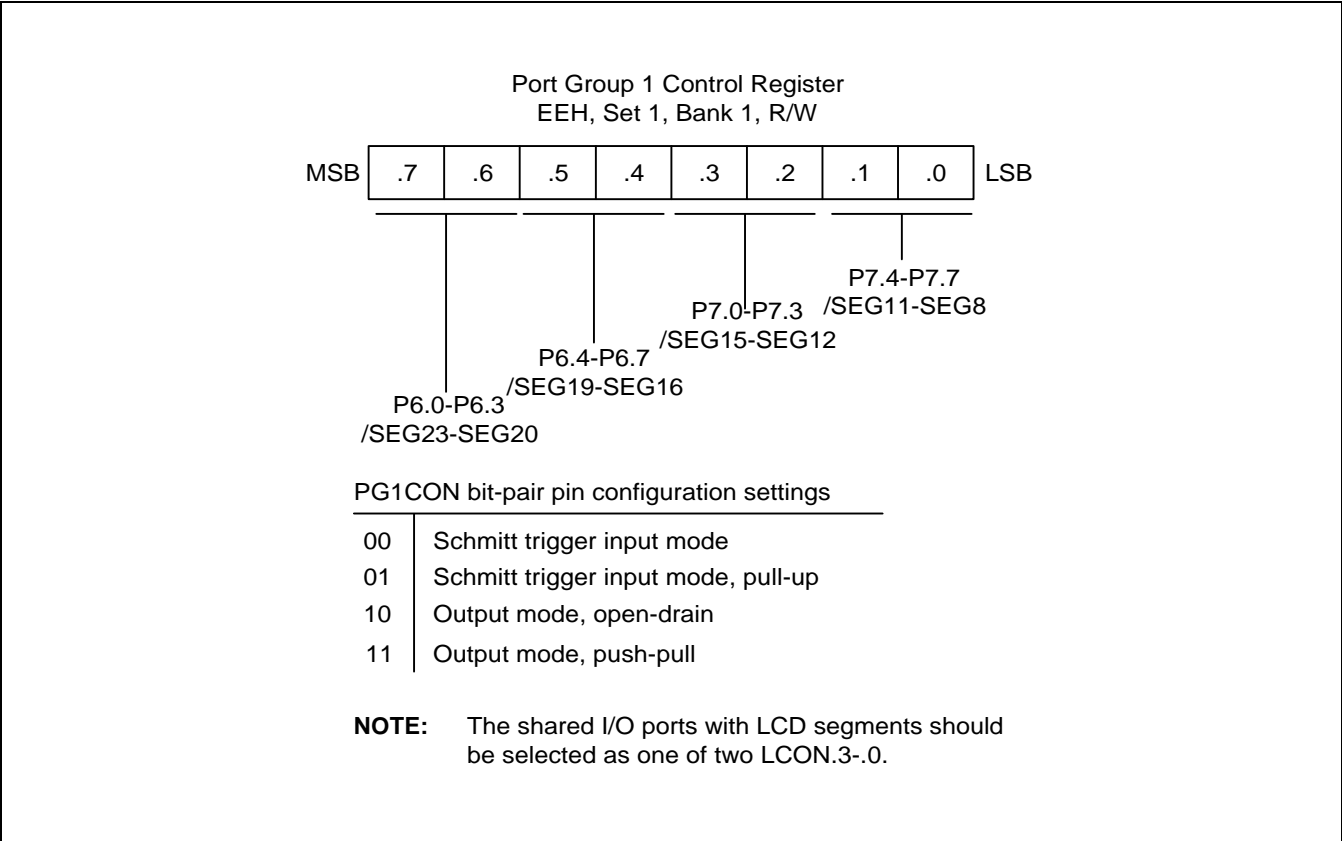

Figure 9-14. Port Group 1 Control Register (PG1CON)

PORT 8

Port 8 is an 8-bit I/O port with nibble configurable pins. Port 8 pins are accessed directly by writing or reading the port 8 data register, P8 at location F8H in set 1, bank 1. P8.0–P8.7 can serve as inputs (with or without pull-ups), as output (open drain or push-pull). And they can serve as segment pins for LCD also.

Port Group 2 Control Register

Port 8 has a 8-bit control register: PG2CON for P8.0–P8.7. A reset clears the PG2CON register to “00H”, configuring all pins to input mode.

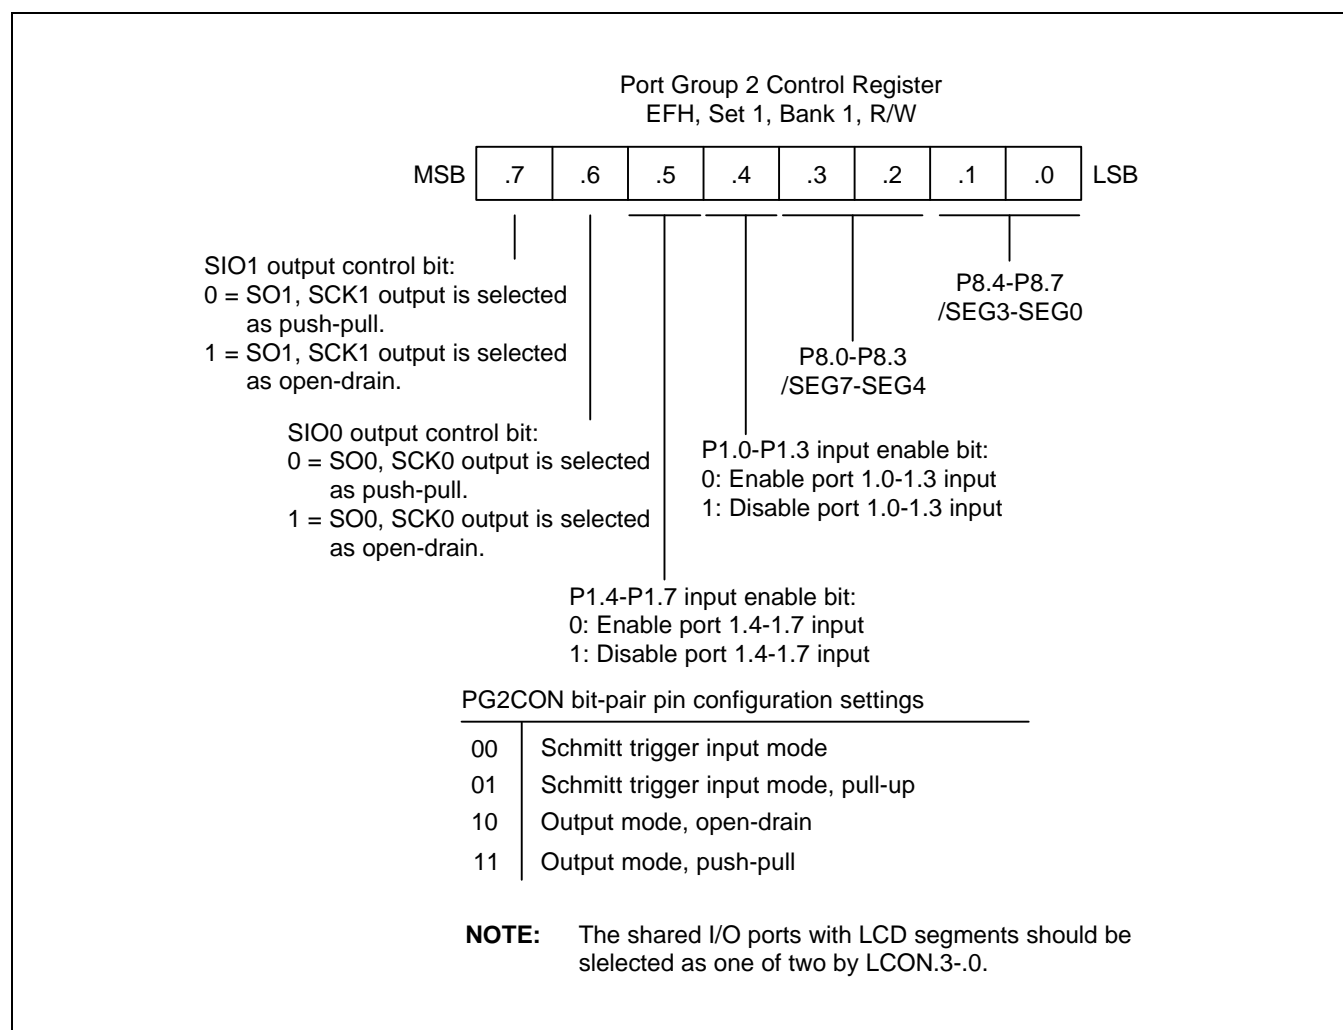

Figure 9-15. Port Group 2 Control Register (PG2CON)

NOTES

10

BASIC TIMER and TIMER 0

OVERVIEW

The S3C831B has two default timers: an 8-bit *basic timer* and one 8-bit general-purpose timer/counter. The 8-bit timer/counter is called *timer 0*.

BASIC TIMER (BT)

You can use the basic timer (BT) in two different ways:

- As a watchdog timer to provide an automatic reset mechanism in the event of a system malfunction.
- To signal the end of the required oscillation stabilization interval after a reset or a stop mode release.

The functional components of the basic timer block are:

- Clock frequency divider (f_{xx} divided by 4096, 1024, 128, or 16) with multiplexer
- 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH, read-only)
- Basic timer control register, BTCON (set 1, D3H, read/write)

BASIC TIMER CONTROL REGISTER (BTCON)

The basic timer control register, BTCON, is used to select the input clock frequency, to clear the basic timer counter and frequency dividers, and to enable or disable the watchdog timer function. It is located in set 1, address D3H, and is read/write addressable using Register addressing mode.

A reset clears BTCON to "00H". This enables the watchdog function and selects a basic timer clock frequency of $f_{xx}/4096$. To disable the watchdog function, you must write the signature code "1010B" to the basic timer register control bits BTCON.7–BTCON.4.

The 8-bit basic timer counter, BTCNT (set 1, bank 0, FDH), can be cleared at any time during normal operation by writing a "1" to BTCON.1. To clear the frequency dividers for all timers input clock, you write a "1" to BTCON.0.

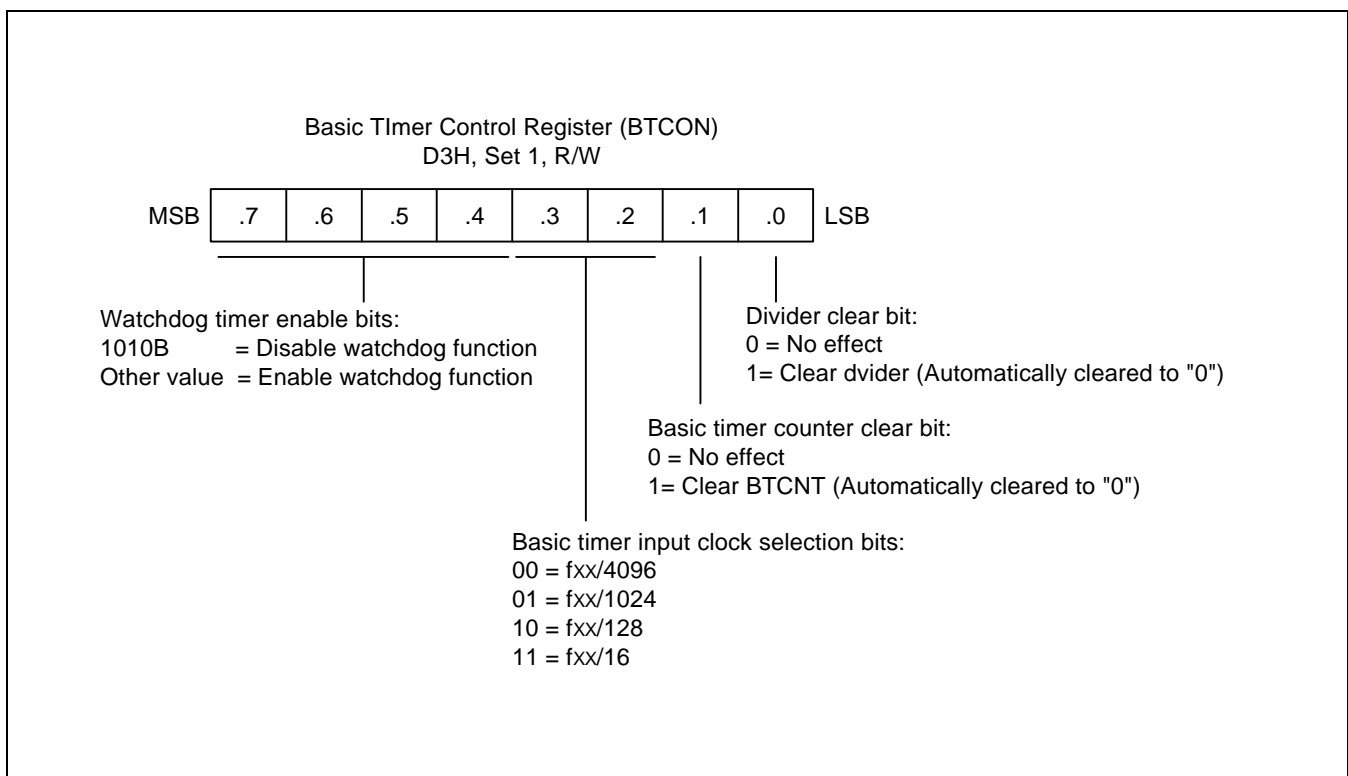

Figure 10-1. Basic Timer Control Register (BTCON)

BASIC TIMER FUNCTION DESCRIPTION

Watchdog Timer Function

You can program the basic timer overflow signal (BTOVF) to generate a reset by setting BTCON.7–BTCON.4 to any value other than “1010B”. (The “1010B” value disables the watchdog function.) A reset clears BTCON to “00H”, automatically enabling the watchdog timer function. A reset also selects the CPU clock (as determined by the current CLKCON register setting), divided by 4096, as the BT clock.

A reset whenever a basic timer counter overflow occurs. During normal operation, the application program must prevent the overflow, and the accompanying reset operation, from occurring. To do this, the BTCNT value must be cleared (by writing a “1” to BTCON.1) at regular intervals.

If a system malfunction occurs due to circuit noise or some other error condition, the BT counter clear operation will not be executed and a basic timer overflow will occur, initiating a reset. In other words, during normal operation, the basic timer overflow loop (a bit 7 overflow of the 8-bit basic timer counter, BTCNT) is always broken by a BTCNT clear instruction. If a malfunction does occur, a reset is triggered automatically.

Oscillation Stabilization Interval Timer Function

You can also use the basic timer to program a specific oscillation stabilization interval following a reset or when stop mode has been released by an external interrupt.

In stop mode, whenever a reset or an internal and an external interrupt occurs, the oscillator starts. The BTCNT value then starts increasing at the rate of $f_{xx}/4096$ (for reset), or at the rate of the preset clock source (for an internal and an external interrupt). When BTCNT.3 overflows, a signal is generated to indicate that the stabilization interval has elapsed and to gate the clock signal off to the CPU so that it can resume normal operation.

In summary, the following events occur when stop mode is released:

1. During stop mode, a power-on reset or an internal and an external interrupt occurs to trigger the stop mode release and oscillation starts.
2. If a power-on reset occurred, the basic timer counter will increase at the rate of $f_{xx}/4096$. If an internal and an external interrupt is used to release stop mode, the BTCNT value increases at the rate of the preset clock source.
3. Clock oscillation stabilization interval begins and continues until bit 3 of the basic timer counter overflows.
4. When a BTCNT.3 overflow occurs, normal CPU operation resumes.

Figure 10-2. Basic Timer Block Diagram

8-BIT TIMER/COUNTER 0

Timer/counter 0 has three operating modes, one of which you select using the appropriate T0CON setting:

- Interval timer mode
- Capture input mode with a rising or falling edge trigger at the P0.2 pin
- PWM mode

Timer/counter 0 has the following functional components:

- Clock frequency divider (f_{xx} divided by 1024, 256, 64, 8, or 1) with multiplexer
- External clock input (P0.1, T0CLK)
- 8-bit counter (T0CNT), 8-bit comparator, and 8-bit reference data register (T0DATA)
- I/O pins for capture input, match output, or PWM output (P0.2/T0CAP, P0.3/T0OUT, P0.3/T0PWM)
- Timer 0 overflow interrupt (IRQ0, vector E2H) and match/capture interrupt (IRQ0, vector E0H) generation
- Timer 0 control register, T0CON (set 1, E2H, bank 0, read/write)

TIMER/COUNTER 0 CONTROL REGISTER (T0CON)

You use the timer 0 control register, T0CON, to

- Select the timer 0 operating mode (interval timer, capture mode, or PWM mode)
- Select the timer 0 input clock frequency
- Clear the timer 0 counter, T0CNT
- Enable the timer 0 overflow interrupt or timer 0 match/capture interrupt
- Clear timer 0 match/capture interrupt pending condition

T0CON is located in set 1, bank 0, at address E2H, and is read/write addressable using Register addressing mode.

A reset clears T0CON to "00H". This sets timer 0 to normal interval timer mode, selects an input clock frequency of $f_{xx}/1024$, and disables all timer 0 interrupts. You can clear the timer 0 counter at any time during normal operation by writing a "1" to T0CON.2.

The timer 0 overflow interrupt (T0OVF) is interrupt level IRQ0 and has the vector address E2H. When a timer 0 overflow interrupt occurs and is serviced by the CPU, the pending condition is cleared automatically by hardware or must be cleared by software.

To enable the timer 0 match/capture interrupt (IRQ0, vector E0H), you must write T0CON.1 to "1". To detect a match/capture interrupt pending condition, the application program polls INTPND.1. When a "1" is detected, a timer 0 match or capture interrupt is pending. When the interrupt request has been serviced, the pending condition must be cleared by software by writing a "0" to the timer 0 match/capture interrupt pending bit, INTPND.1.

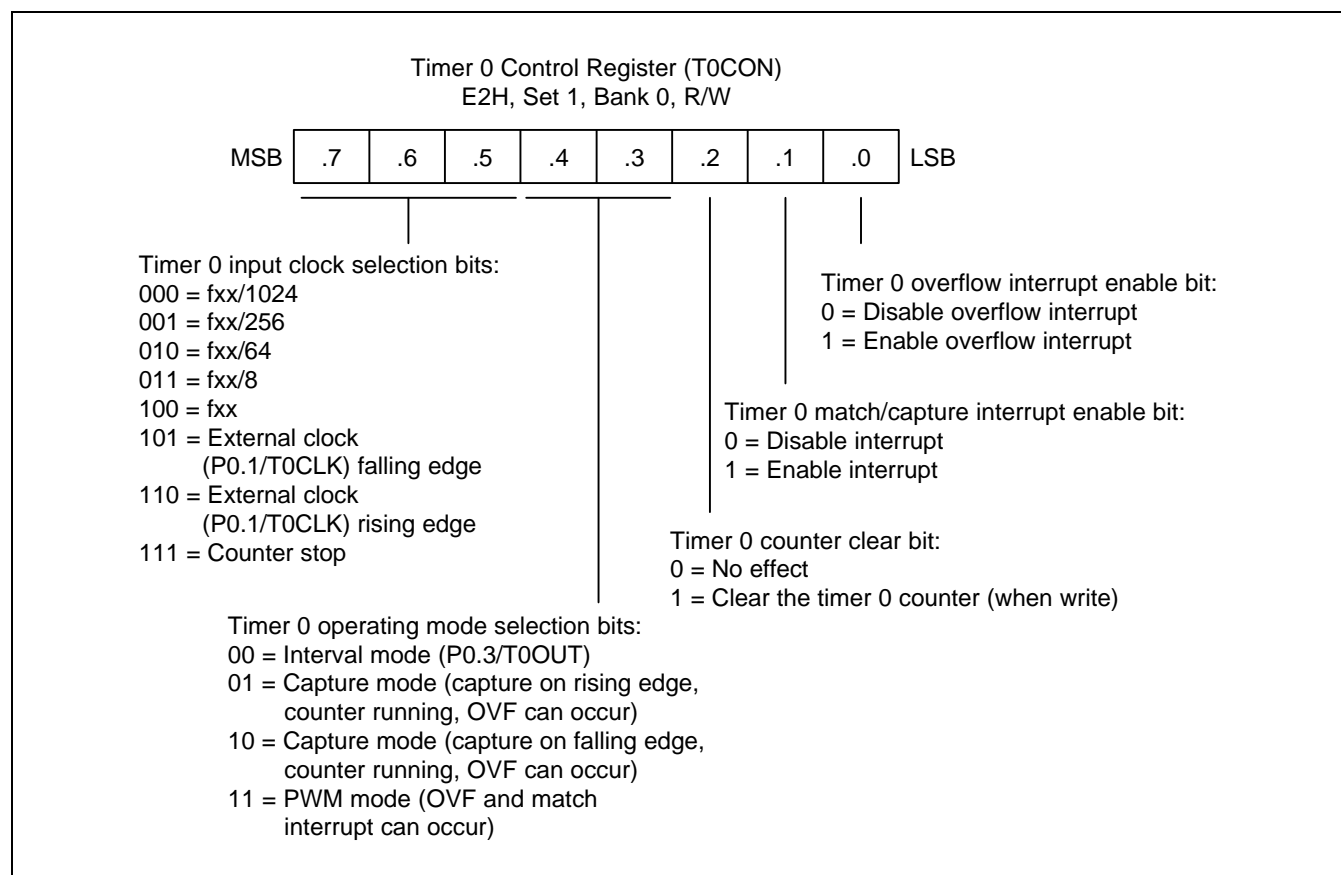

Figure 10-3. Timer 0 Control Register (T0CON)

Figure 10-4. Timer 0 Interrupt Pending Register (INTPND)

TIMER 0 FUNCTION DESCRIPTION

Timer 0 Interrupts (IRQ0, Vectors E0H and E2H)

The timer 0 can generate two interrupts: the timer 0 overflow interrupt (T0OVF), and the timer 0 match/ capture interrupt (T0INT). T0OVF belongs to interrupt level IRQ0, vector E2H. T0INT also belongs to interrupt level IRQ0, but is assigned the separate vector address, E0H.

A timer 0 overflow interrupt pending condition is automatically cleared by hardware when it has been serviced or should be cleared by software in the interrupt service routine by writing a "0" to the INTPND.0 interrupt pending bit. However, the timer 0 match/capture interrupt pending condition must be cleared by the application's interrupt service routine by writing a "0" to the INTPND.1 interrupt pending bit.

Interval Timer Mode

In interval timer mode, a match signal is generated when the counter value is identical to the value written to the timer 0 reference data register, T0DATA. The match signal generates a timer 0 match interrupt (T0INT, vector E0H) and clears the counter.

If, for example, you write the value "10H" to T0DATA, the counter will increment until it reaches "10H". At this point, the timer 0 interrupt request is generated, the counter value is reset, and counting resumes. With each match, the level of the signal at the timer 0 output pin is inverted (see Figure 10-5).

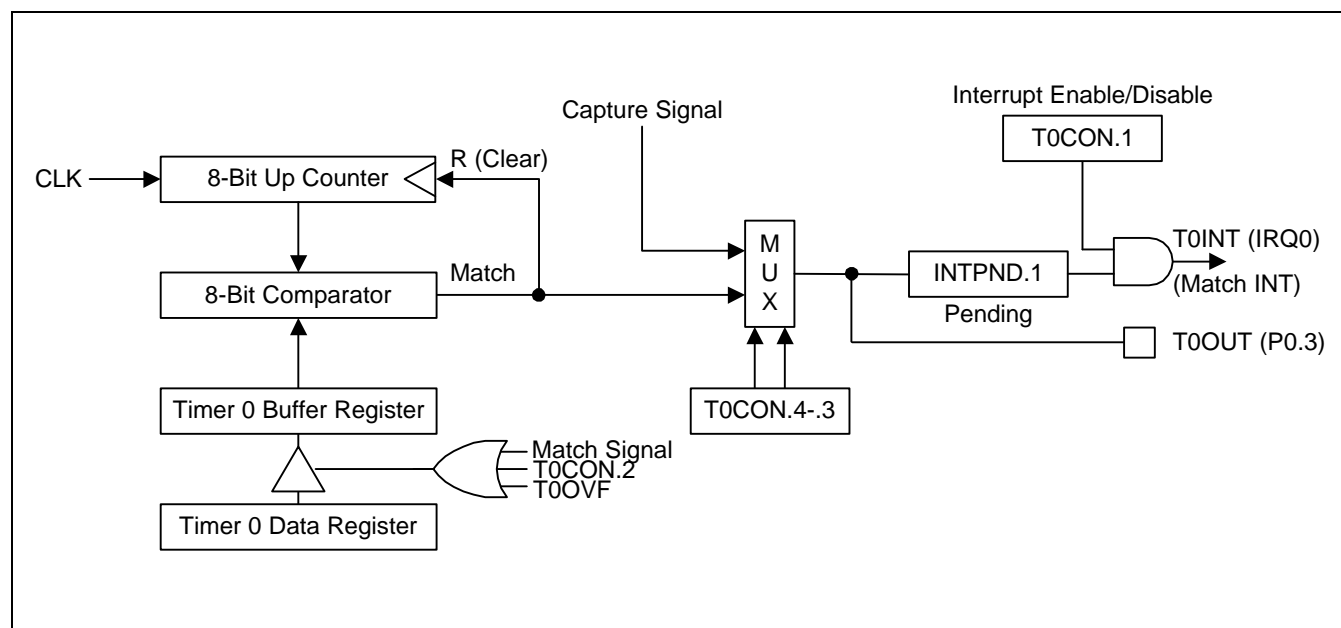

Figure 10-5. Simplified Timer 0 Function Diagram: Interval Timer Mode

Pulse Width Modulation Mode

Pulse width modulation (PWM) mode lets you program the width (duration) of the pulse that is output at the TOPWM (P0.3) pin. As in interval timer mode, a match signal is generated when the counter value is identical to the value written to the timer 0 data register. In PWM mode, however, the match signal does not clear the counter. Instead, it runs continuously, overflowing at "FFH", and then continues incrementing from "00H".

Although you can use the match signal to generate a timer 0 overflow interrupt, interrupts are not typically used in PWM-type applications. Instead, the pulse at the TOPWM (P0.3) pin is held to Low level as long as the reference data value is *less than or equal to* (\leq) the counter value and then the pulse is held to High level for as long as the data value is *greater than* ($>$) the counter value. One pulse width is equal to $t_{CLK} \times 256$ (see Figure 10-6).

Figure 10-6. Simplified Timer 0 Function Diagram: PWM Mode

Capture Mode

In capture mode, a signal edge that is detected at the T0CAP (P0.2) pin opens a gate and loads the current counter value into the timer 0 data register. You can select rising or falling edges to trigger this operation.

Timer 0 also gives you capture input source: the signal edge at the T0CAP (P0.2) pin. You select the capture input by setting the values of the timer 0 capture input selection bits in the port 0 control register, P0CONL.5–.4, (set 1, bank 1, E1H). When P0CONL.5–.4 is "00", the T0CAP input is selected.

Both kinds of timer 0 interrupts can be used in capture mode: the timer 0 overflow interrupt is generated whenever a counter overflow occurs; the timer 0 match/capture interrupt is generated whenever the counter value is loaded into the timer 0 data register.

By reading the captured data value in T0DATA, and assuming a specific value for the timer 0 clock frequency, you can calculate the pulse width (duration) of the signal that is being input at the T0CAP pin (see Figure 10-7).

NOTES

11

8-BIT TIMER 1

OVERVIEW

The 8-bit timer 1 is an 8-bit general-purpose timer. Timer 1 has the interval timer mode by using the appropriate T1CON setting.

Timer 1 has the following functional components:

- Clock frequency divider (f_{xx} divided by 256, 64, 8 or 1) with multiplexer
- External clock input (P0.4/T1CLK)
- 8-bit counter (T1CNT), 8-bit comparator, and 8-bit reference data register (T1DATA)
- Timer 1 interrupt (IRQ1, vector E6H) generation
- Timer 1 control register, T1CON (set 1, Bank 0, E5H, read/write)

FUNCTION DESCRIPTION

Interval Timer Function

The timer 1 can generate an interrupt, the timer 1 match interrupt (T1INT). T1INT belongs to interrupt level IRQ1, and is assigned the separate vector address, E6H.

The T1INT pending condition should be cleared by software when it has been serviced. Even though T1INT is disabled, the application's service routine can detect a pending condition of T1INT by the software and execute its sub-routine. When this case is used, the T1INT pending bit must be cleared by the application subroutine by writing a "0" to the T1CON.0 pending bit.

In interval timer mode, a match signal is generated when the counter value is identical to the values written to the Timer 1 reference data registers, T1DATA. The match signal generates a timer 1 match interrupt (T1INT, vector E6H) and clears the counter.

If, for example, you write the value 10H to T1DATA and 0EH to T1CON, the counter will increment until it reaches 10H. At this point, the Timer 1 interrupt request is generated, the counter value is reset, and counting resumes.

TIMER 1 CONTROL REGISTER (T1CON)

You use the timer 1 control register, T1CON, to

- Enable the timer 1 operating (interval timer)
- Select the timer 1 input clock frequency
- Clear the timer 1 counter, T1CNT
- Enable the timer 1 interrupt and clear timer 1 interrupt pending condition

T1CON is located in set 1, bank 0, at address E5H, and is read/write addressable using register addressing mode.

A reset clears T1CON to "00H". This sets timer 1 to disable interval timer mode, and disables timer 1 interrupt. You can clear the timer 1 counter at any time during normal operation by writing a "1" to T1CON.3

To enable the timer 1 interrupt (IRQ1, vector E6H), you must write T1CON.2, and T1CON.1 to "1". To detect an interrupt pending condition when T1INT is disabled, the application program polls pending bit, T1CON.0. When a "1" is detected, a timer 1 interrupt is pending. When the T1INT sub-routine has been serviced, the pending condition must be cleared by software by writing a "0" to the timer 1 interrupt pending bit, T1CON.0.

NOTES

12

16-BIT TIMER 2

OVERVIEW

The 16-bit timer 2 is an 16-bit general-purpose timer. Timer 2 has the interval timer mode by using the appropriate T2CON setting.

Timer 2 has the following functional components:

- Clock frequency divider (f_{xx} divided by 256, 64, 8 or 1) with multiplexer
- External clock input (T2CLK)
- 16-bit counter (T2CNTH/L), 16-bit comparator, and 16-bit reference data register (T2DATAH/L)
- Timer 2 interrupt (IRQ1, vector E4H) generation
- Timer 2 control register, T2CON (set 1, Bank 1, FEH, read/write)

FUNCTION DESCRIPTION

Interval Timer Function

The timer 2 can generate an interrupt, the timer 2 match interrupt (T2INT). T2INT belongs to interrupt level IRQ1, and is assigned the separate vector address, E4H.

The T2INT pending condition should be cleared by software when it has been serviced. Even though T2INT is disabled, the application's service routine can detect a pending condition of T2INT by the software and execute its sub-routine. When this case is used, the T2INT pending bit must be cleared by the application subroutine by writing a "0" to the T2CON.0 pending bit.

In interval timer mode, a match signal is generated when the counter value is identical to the values written to the Timer 2 reference data registers, T2DATA. The match signal generates a timer 2 match interrupt (T2INT, vector E4H) and clears the counter.

If, for example, you write the value 0010H to T2DATAH/L and 0EH to T2CON, the counter will increment until it reaches 10H. At this point, the Timer 2 interrupt request is generated, the counter value is reset, and counting resumes.

TIMER 2 CONTROL REGISTER (T2CON)

You use the timer 2 control register, T2CON, to

- Enable the timer 2 operating (interval timer)
- Select the timer 2 input clock frequency
- Clear the timer 2 counter, T2CNTH/L
- Enable the timer 2 interrupt and clear timer 2 interrupt pending condition

T2CON is located in set 1, bank 1, at address FEH, and is read/write addressable using register addressing mode.

A reset clears T2CON to "00H". This sets timer 2 to disable interval timer mode, and disables timer 2 interrupt. You can clear the timer 2 counter at any time during normal operation by writing a "1" to T2CON.3

To enable the timer 2 interrupt (IRQ1, vector E4H), you must write T2CON.2, and T2CON.1 to "1". To detect an interrupt pending condition when T2INT is disabled, the application program polls pending bit, T2CON.0. When a "1" is detected, a timer 2 interrupt is pending. When the T2INT sub-routine has been serviced, the pending condition must be cleared by software by writing a "0" to the timer 2 interrupt pending bit, T2CON.0.

13

WATCH TIMER

OVERVIEW

Watch timer functions include real-time and watch-time measurement and interval timing for the system clock. To start watch timer operation, set bit 6 of the watch timer control register, WTCN.6 to "1". And if you want to service watch timer overflow interrupt (IRQ3, vector F2H), then set the WTCN.1 to "1". The watch timer overflow interrupt pending condition (WTCN.0) must be cleared by software in the application's interrupt service routine by means of writing a "0" to the WTCN.0 interrupt pending bit. After the watch timer starts and elapses a time, the watch timer interrupt pending bit (WTCN.0) is automatically set to "1", and interrupt requests commence in 50 ms, 0.5 and 1-second intervals by setting Watch timer speed selection bits (WTCN.3 – .2).

The watch timer can generate a steady 1 kHz, 1.5 kHz, 3 kHz, or 6 kHz signal to BUZ output pin for Buzzer. By setting WTCN.3 and WTCN.2 to "11b", the watch timer will function in high-speed mode, generating an interrupt every 50 ms. High-speed mode is useful for timing events for program debugging sequences.

The watch timer supplies the clock frequency for the LCD controller (f_{LCD}). Therefore, if the watch timer is disabled, the LCD controller does not operate.

Watch timer has the following functional components:

- Real Time and Watch-Time Measurement
- Using a Main System Clock Source only
- Clock Source Generation for LCD Controller (f_{LCD})
- I/O pin for Buzzer Output Frequency Generator (P3.0, BUZ)
- Timing Tests in High-Speed Mode
- Watch timer overflow interrupt (IRQ3, vector F2H) generation
- Watch timer control register, WTCN (set 1, bank 0, E8H, read/write)

WATCH TIMER CONTROL REGISTER (WTCN)

The watch timer control register, WTCN is used to select the watch timer interrupt time and Buzzer signal, to enable or disable the watch timer function. It is located in set 1, bank 0 at address E8H, and is read/write addressable using register addressing mode.

A reset clears WTCN to "00H". This disable the watch timer.

So, if you want to use the watch timer, you must write appropriate value to WTCN.

LCD CONTROLLER/DRIVER

OVERVIEW

The S3C831B microcontroller can directly drive an up-to-20-digit (40-segment) LCD panel. The LCD block has the following components:

- LCD controller/driver
- Display RAM (00H–13H) for storing display data in page 9
- 40 segment output pins (SEG0–SEG39)
- Four common output pins (COM0–COM3)
- Three LCD operating power supply pins (V_{LC0} – V_{LC2}) and bias pin for LCD driving voltage (V_{LCD})
- LCD voltage dividing resistors

Bit settings in the LCD mode register, LMOD, determine the LCD frame frequency, duty and bias, and LCD voltage dividing resistors.

The LCD control register LCON turns the LCD display on and off and switches current to the LCD voltage dividing resistors for the display. LCD data stored in the display RAM locations are transferred to the segment signal pins automatically without program control.

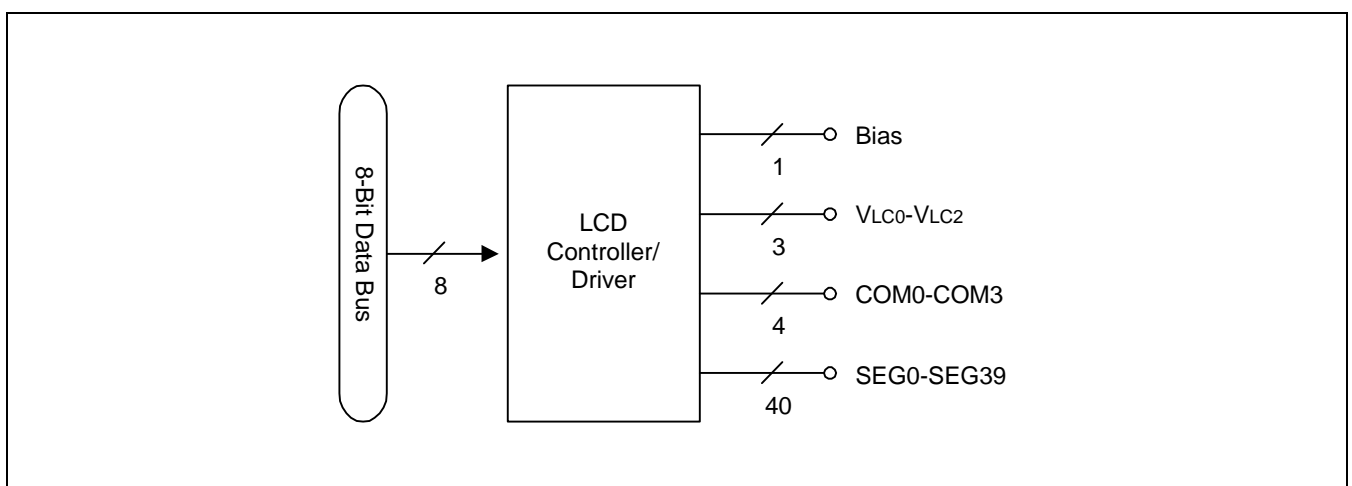

Figure 14-1. LCD Function Diagram

LCD CIRCUIT DIAGRAM

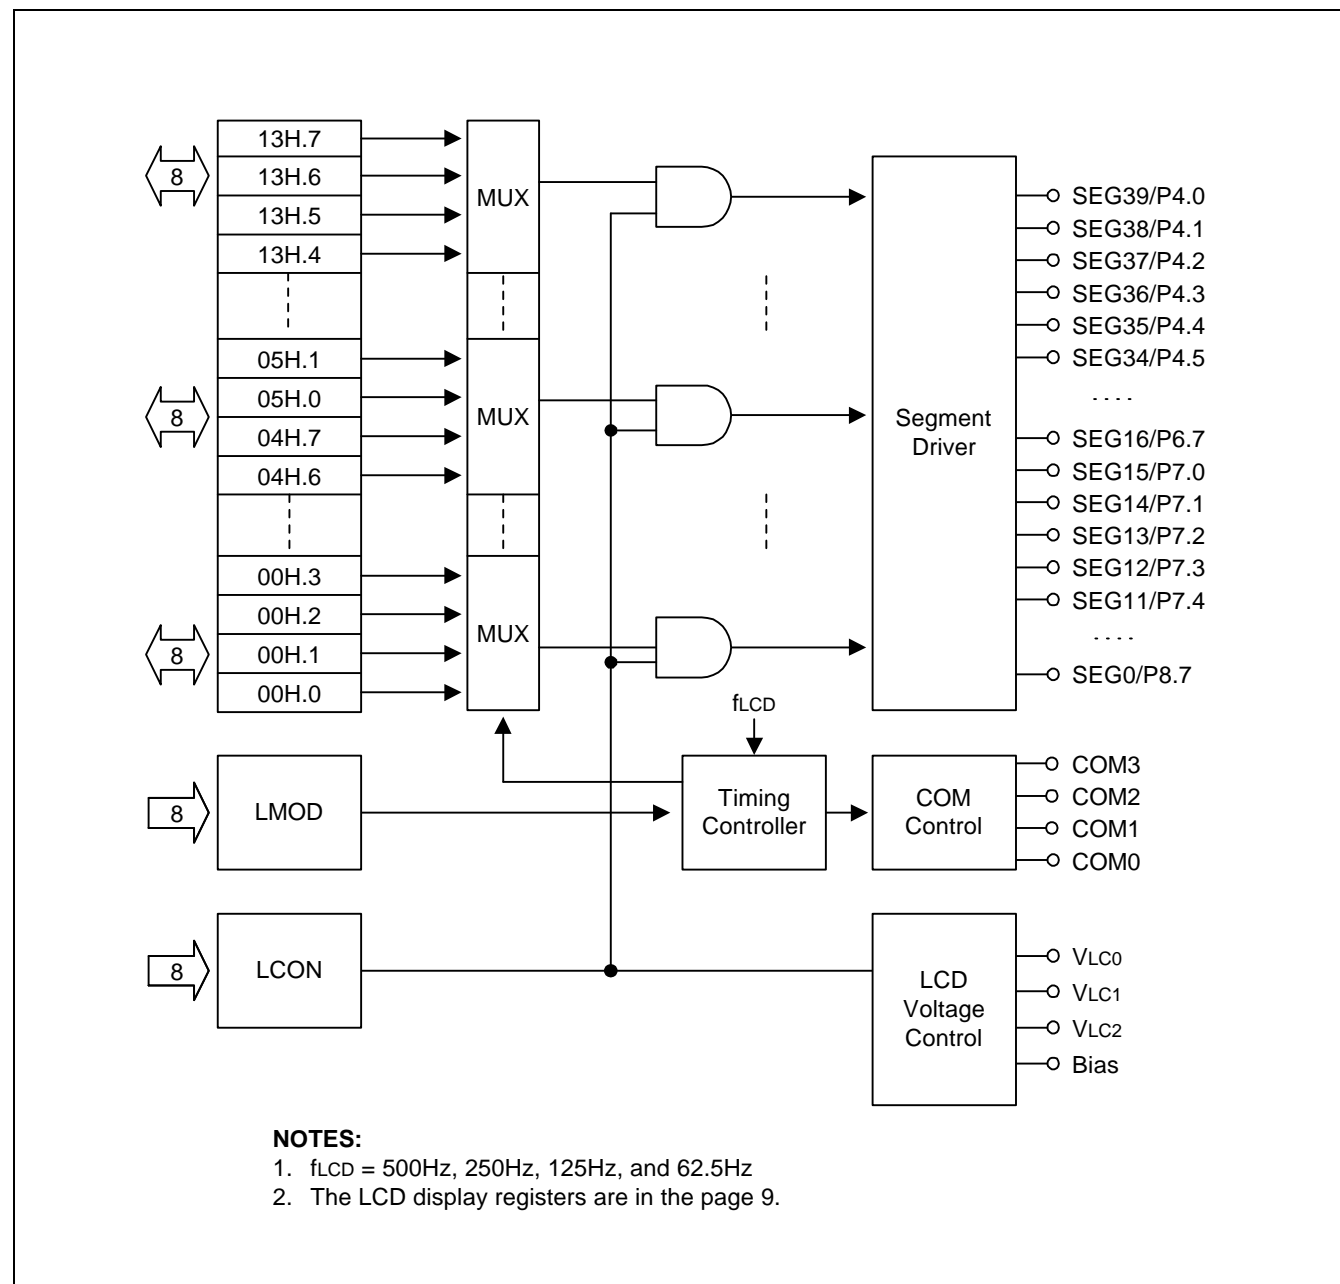

Figure 14-2. LCD Circuit Diagram

LCD RAM ADDRESS AREA

RAM addresses 00H–13H of page 9 are used as LCD data memory. When the bit value of a display segment is "1", the LCD display is turned on; when the bit value is "0", the display is turned off.

Display RAM data are sent out through segment pins SEG0–SEG39 using a direct memory access (DMA) method that is synchronized with the f_{LCD} signal. RAM addresses in this location that are not used for LCD display can be allocated to general-purpose use.

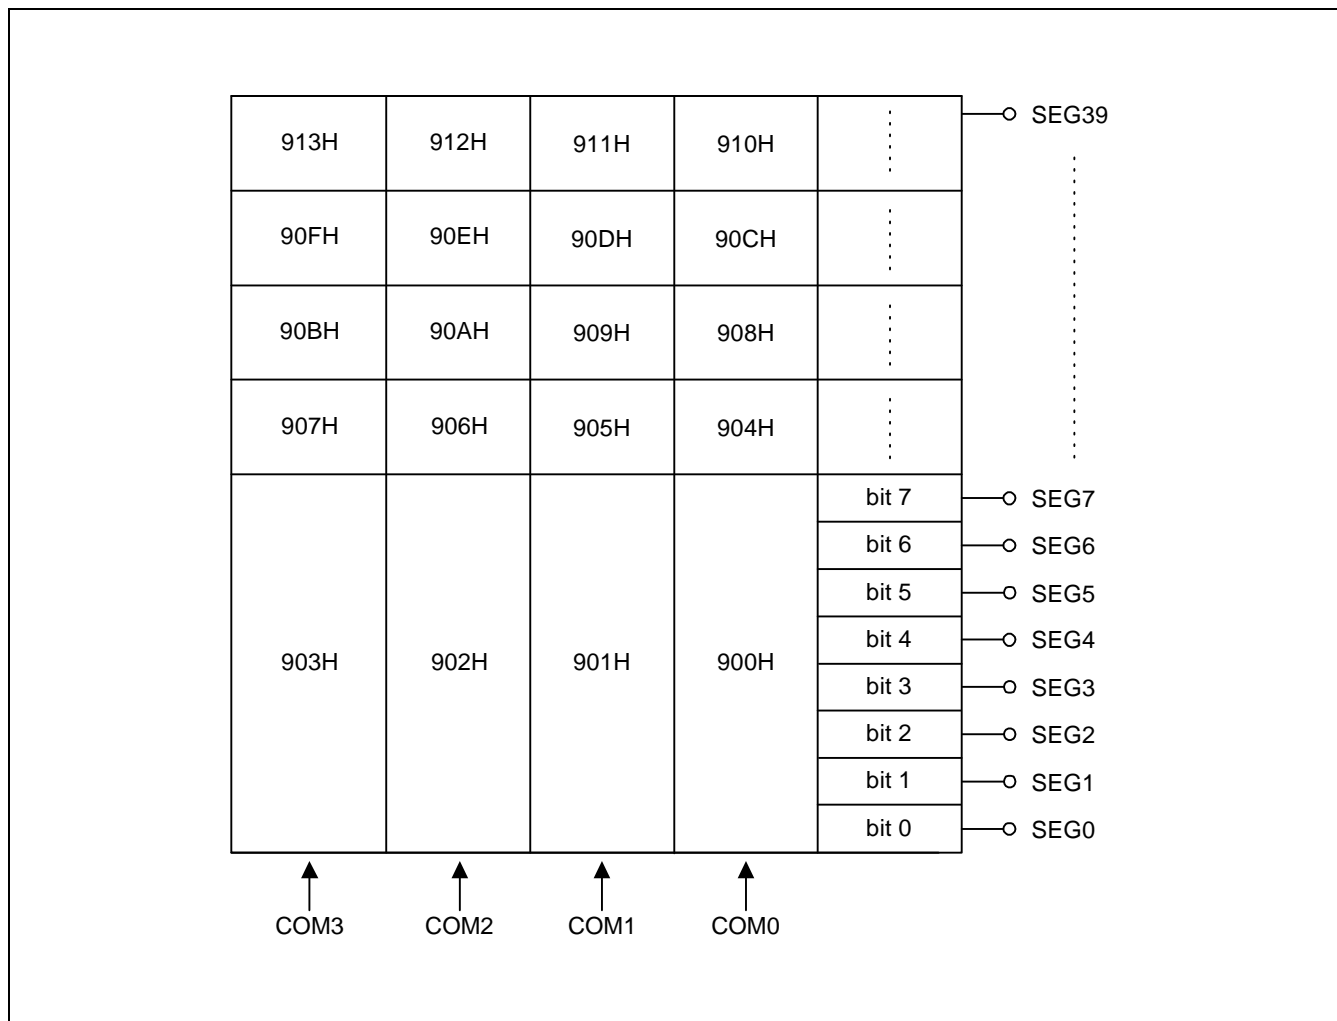

Figure 14-3. LCD Display Data RAM Organization

LCD CONTROL REGISTER (LCON), F1H at BANK 0 of SET 1

Table 14-1. LCD Control Register (LCON) Organization

LCON Bit	Setting	Description
LCON.7	0	LCD output is low and the current for dividing the resistors is cut off.
	1	If LMOD.3 = "0", LCD display is turned off. (All LCD segments are off signal output.) If LMOD.3 = "1", output COM and SEG signals in display mode.
LCON.6-.4	Not used for the S3C831B.	
LCON.3-.0	0000	Select LCD SEG0-39.
	0001	Select LCD SEG0-35/P4.0-4.3 as I/O port.
	0010	Select LCD SEG0-31/P4 as I/O port.
	0011	Select LCD SEG0-27/P4, P5.0-P5.3 as I/O port.
	0100	Select LCD SEG0-23/P4, P5 as I/O port.
	0101	Select LCD SEG0-19/P4, P5, P6.0-P6.3 as I/O port.
	0110	Select LCD SEG0-15/P4, P5, P6 as I/O port.
	0111	Select LCD SEG0-11/P4, P5, P6, P7.0-P7.3 as I/O port.
	1000	Select LCD SEG0-7/P4, P5, P6, P7 as I/O port.
	1001	Select LCD SEG0-3/P4, P5, P6, P7, P8.0-P8.3 as I/O port.
	1010	All I/O port (P4-P8)

LCD MODE REGISTER (LMOD)

The LCD mode control register LMOD is mapped to RAM address F2H at bank 0 of set 1.

LMOD controls these LCD functions:

- Duty and bias selection (LMOD.3–LMOD.0)
- LCDCK clock frequency selection (LMOD.5–LMOD.4)
- LCD voltage dividing resistors selection (LMOD.6)
- LCD common signal enable or disable selection (LMOD.7)

The LCD clock signal, LCDCK, determines the frequency of COM signal scanning of each segment output. This is also referred to as the 'frame frequency.' Since LCDCK is generated by dividing the watch timer clock (fw), the watch timer must be enabled when the LCD display is turned on. RESET clears the LMOD register values to logic zero. This produces the following LCD control settings:

- Display is turned off
- LCDCK frequency is 62.5 Hz (at $f_x = 4.5$ MHz) from the watch timer clock.

The LCD display can continue to operate during idle mode.

Table 14-2. LCD Clock Signal (LCDCK) Frame Frequency

LCDCK Frequency	Static	1/2 Duty	1/3 Duty	1/4 Duty
62.5 Hz	62.5 Hz	31.3 Hz	20.8 Hz	15.6 Hz
125 Hz	125 Hz	62.5 Hz	41.7 Hz	31.3 Hz
250 Hz	250 Hz	125 Hz	83.3 Hz	62.5 Hz
500 Hz	500 Hz	250 Hz	166.7 Hz	125 Hz

NOTE: $f_x = 4.5$ MHz

Table 14-3. LCD Mode Control Register (LMOD) Organization, F2H at Bank 0 of Set 1

LMOD.7	COM Signal Enable/Disable Bit
0	Enable COM signal
1	Disable COM signal

LMOD.6	LCD Voltage Dividing Resistors Control Bit
0	Internal voltage dividing resistors
1	External voltage dividing resistors; Internal voltage dividing resistors are off.

LMOD.5	LMOD.4	LCD Clock (LCDCK) Frequency (When fxx = 4.5MHz)
0	0	62.5 Hz at fx = 4.5 MHz
0	1	125 Hz at fx = 4.5 MHz
1	0	250 Hz at fx = 4.5 MHz
1	1	500 Hz at fx = 4.5 MHz

NOTE: If the main clock is 9.0MHz, IFMOD.7 should be set to "1".

LMOD.3	LMOD.2	LMOD.1	LMOD.0	Duty and Bias Selection for LCD Display
0	x	x	x	LCD display off (LCD off signal output)
1	0	0	0	1/4 duty, 1/3 bias
1	0	0	1	1/3 duty, 1/3 bias
1	0	1	1	1/3 duty, 1/2 bias
1	0	1	0	1/2 duty, 1/2 bias
1	1	0	0	Static

Table 14-4. Maximum Number of Display Digits per Duty Cycle

LCD Duty	LCD Bias	COM Output Pins	Maximum Seg Display
Static	Static	COM0	40
1/2	1/2	COM0–COM1	40 x 2
1/3	1/2	COM0–COM2	40 x 3
1/3	1/3	COM0–COM2	40 x 3
1/4	1/3	COM0–COM3	40 x 4

LCD DRIVE VOLTAGE

The LCD display is turned on only when the voltage difference between the common and segment signals is greater than V_{LCD} . The LCD display is turned off when the difference between the common and segment signal voltages is less than V_{LCD} . The turn-on voltage, $+V_{LCD}$ or $-V_{LCD}$, is generated only when both signals are the selected signals of the bias. Table 14-5 shows LCD drive voltages for static mode, 1/2 bias, and 1/3 bias.

Table 14-5. LCD Drive Voltage Values

LCD Power Supply	Static Mode	1/2 Bias	1/3 Bias
V_{LC0}	V_{LCD}	V_{LCD}	V_{LCD}
V_{LC1}	—	$1/2 V_{LCD}$	$2/3 V_{LCD}$
V_{LC2}	—	$1/2 V_{LCD}$	$1/3 V_{LCD}$
V_{ss}	0 V	0 V	0 V

NOTE: The LCD panel display may deteriorate if a DC voltage is applied that lies between the common and segment signal voltage. Therefore, always drive the LCD panel with AC voltage.

LCD COM/SEG SIGNALS

The 40 LCD segment signal pins are connected to corresponding display RAM locations at 00H–13H at page 7. The corresponding bits of the display RAM are synchronized with the common signal output pins COM0, COM1, COM2, and COM3.

When the bit value of a display RAM location is "1", a select signal is sent to the corresponding segment pin. When the display bit is "0", a 'no-select' signal is sent to the corresponding segment pin. Each bias has select and no-select signals.

Figure 14-4. Select/No-Select Bias Signals in Static Display Mode

Figure 14-5. Select/No-Select Bias Signals in 1/2 Duty, 1/2 Bias Display Mode

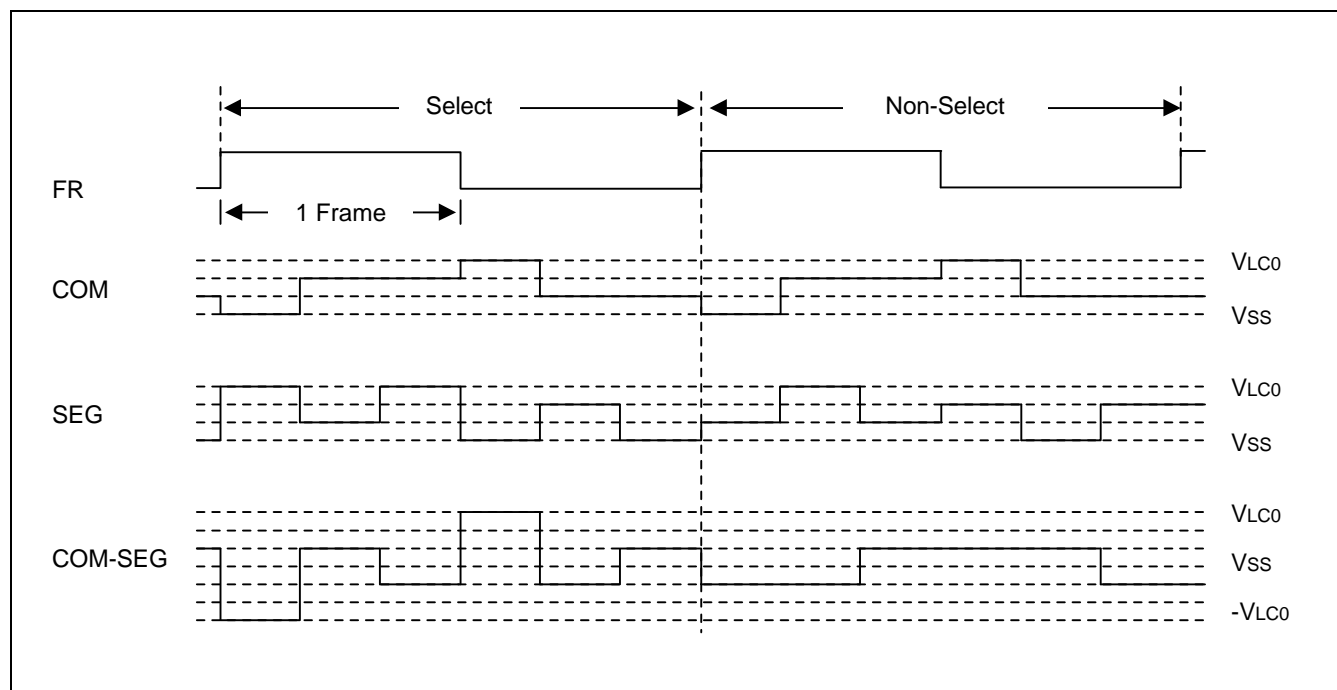

Figure 14-6. Select/No-Select Bias Signals in 1/3 Duty, 1/3 Bias Display Mode

Static and 1/3 Bias ($V_{LCD} = 3\text{ V}$ at $V_{DD} = 5\text{ V}$)1/2 Bias ($V_{LCD} = 2.5\text{ V}$ at $V_{DD} = 5\text{ V}$)Static and 1/3 Bias ($V_{LCD} = 5\text{ V}$ at $V_{DD} = 5\text{ V}$)

Voltage Dividing Resistors Adjustment

$$V_{LCD} = \frac{3 R' \times V_{DD}}{R'' + 3R'} \quad , \text{ when LMOD.6} = "1"$$

NOTES:

1. R = Internal voltage dividing resistors. These resistors can be disconnected by LMOD.6.
2. R' = External Resistors
3. R'' = External Resistor to adjust V_{LCD} .

8-BIT ANALOG-TO-DIGITAL CONVERTER

OVERVIEW

The 8-bit A/D converter (ADC) module uses successive approximation logic to convert analog levels entering at one of the eight input channels to equivalent 8-bit digital values. The analog input level must lie between the AV_{DD} and V_{SS} values. The A/D converter has the following components:

- Analog comparator with successive approximation logic
- D/A converter logic (resistor string type)
- ADC control register (ADCON)
- Eight multiplexed analog data input pins (AD0–AD7)
- 8-bit A/D conversion data output register (ADDATA)
- 8-bit digital input port (Alternately, I/O port.)
- AV_{DD} pin is internally connected to V_{DD} .

FUNCTION DESCRIPTION

To initiate an analog-to-digital conversion procedure, at first you must set with alternative function for ADC input enable at port 2, the pin set with alternative function can be used for ADC analog input. And you write the channel selection data in the A/D converter control register ADCON.4–.6 to select one of the eight analog input pins (AD0–7) and set the conversion start or enable bit, ADCON.0. The read-write ADCON register is located in set 1, bank 0, at address EFH. The pins which are not used for ADC can be used for normal I/O.

During a normal conversion, ADC logic initially sets the successive approximation register to 80H (the approximate half-way point of an 8-bit register). This register is then updated automatically during each conversion step. The successive approximation block performs 8-bit conversions for one input channel at a time. You can dynamically select different channels by manipulating the channel selection bit value (ADCON.6–4) in the ADCON register. To start the A/D conversion, you should set the enable bit, ADCON.0. When a conversion is completed, ADCON.3, the end-of-conversion(EOC) bit is automatically set to 1 and the result is dumped into the ADDATA register where it can be read. The A/D converter then enters an idle state. Remember to read the contents of ADDATA before another conversion starts. Otherwise, the previous result will be overwritten by the next conversion result.

NOTE

Because the A/D converter has no sample-and-hold circuitry, it is very important that fluctuation in the analog level at the AD0–AD7 input pins during a conversion procedure be kept to an absolute minimum. Any change in the input level, perhaps due to noise, will invalidate the result. If the chip enters to STOP or IDLE mode in conversion process, there will be a leakage current path in A/D block. You must use STOP or IDLE mode after ADC operation is finished.

CONVERSION TIMING

The A/D conversion process requires 5 steps (5 clock edges) to convert each bit and 10 clocks to set-up A/D conversion. Therefore, total of 50 clocks are required to complete an 8-bit conversion: When fxx/8 is selected for conversion clock with an 4.5 MHz fxx clock frequency, one clock cycle is 1.78 us. Each bit conversion requires 5 clocks, the conversion rate is calculated as follows:

$$5 \text{ clocks/bit} \times 8 \text{ bits} + \text{set-up time} = 50 \text{ clocks}, 50 \text{ clock} \times 1.78 \text{ us} = 89 \text{ us at } 0.56 \text{ MHz (4.5 MHz/8)}$$

Note that A/D converter needs at least 25μs for conversion time.

A/D CONVERTER CONTROL REGISTER (ADCON)

The A/D converter control register, ADCON, is located at address EFH in set 1, bank 0. It has three functions:

- Analog input pin selection (bits 4, 5, and 6)
- End-of-conversion status detection (bit 3)
- ADC clock selection (bits 2 and 1)
- A/D operation start or enable (bit 0)

After a reset, the start bit is turned off. You can select only one analog input channel at a time. Other analog input pins (AD0–AD7) can be selected dynamically by manipulating the ADCON.4–6 bits. And the pins not used for analog input can be used for normal I/O function.

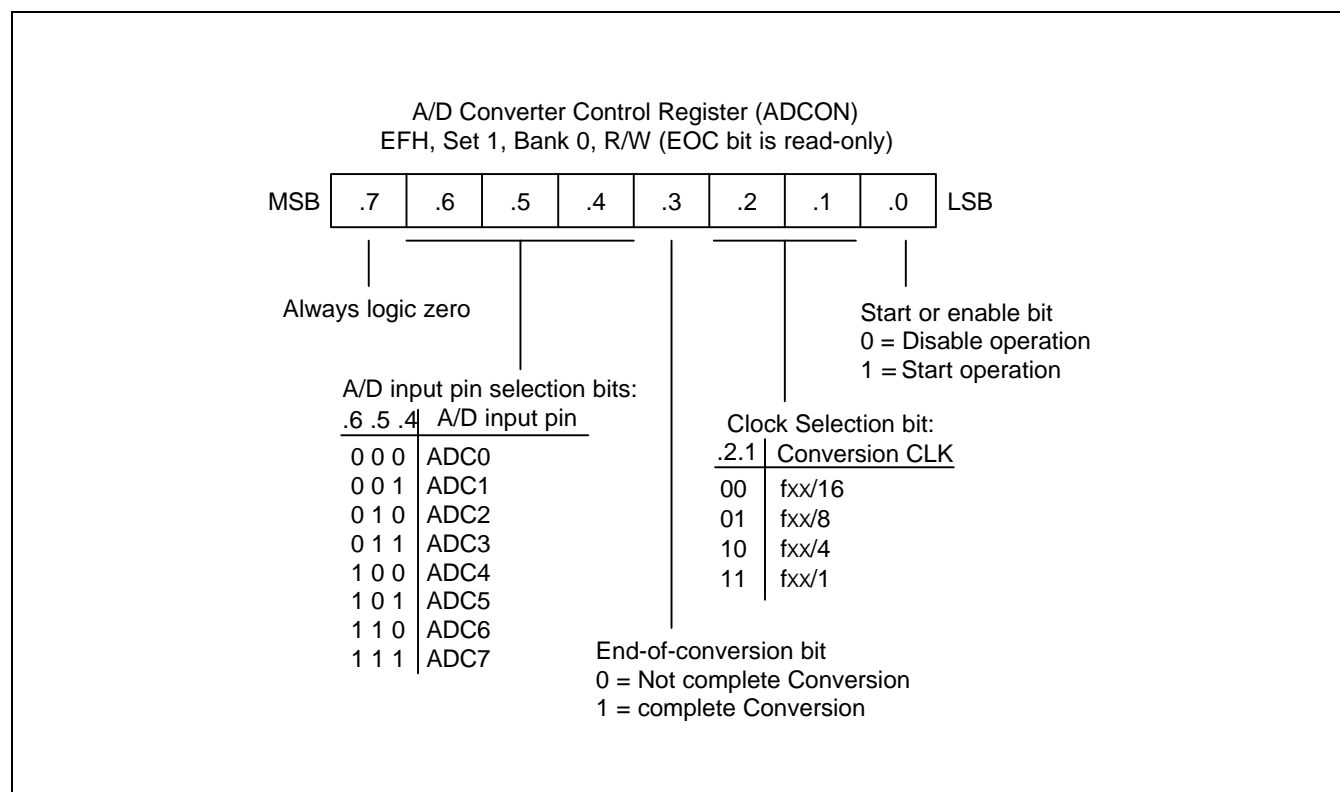

Figure 15-1. A/D Converter Control Register (ADCON)

Figure 15-2. A/D Converter Data Register (ADDATA)

INTERNAL REFERENCE VOLTAGE LEVELS

In the ADC function block, the analog input voltage level is compared to the reference voltage. The analog input level must remain within the range V_{SS} to AV_{DD} (The AV_{DD} pin is internally connected with V_{DD}).

Different reference voltage levels are generated internally along the resistor tree during the analog conversion process for each conversion step. The reference voltage level for the first conversion bit is always $1/2 AV_{DD}$.

SERIAL I/O INTERFACE

OVERVIEW

Serial I/O modules, SIO0 and SIO1 can interface with various types of external device that require serial data transfer. The components of SIO0 and SIO1 function block are:

- 8-bit control register (SIO0CON, SIO1CON)
- Clock selector logic
- 8-bit data buffer (SIO0DATA, SIO1DATA)
- 8-bit prescaler (SIO0PS, SIO1PS)
- 3-bit serial clock counter
- Serial data I/O pins (SI0, SO0, SI1, SO1)
- Serial clock input/output pins (SCK0, SCK1)
- Serial data and clock output type selection (PG2CON.7–.6)

The SIO modules can transmit or receive 8-bit serial data at a frequency determined by its corresponding control register settings. To ensure flexible data transmission rates, you can select an internal or external clock source.

PROGRAMMING PROCEDURE

To program the SIO modules, follow these basic steps:

1. Configure the I/O pins at port (SCK0/SI0/SO0, SCK1/SI1/SO1) by loading the appropriate value to the P3CONH and P3CONL register if necessary.
2. Configure the output type (SCK0/SO0, SCK1/SO1) by manipulating PG2CON.7–.6 if necessary.
3. Load an 8-bit value to the SIO0CON and SIO1CON control registers to properly configure the serial I/O modules. In this operation, SIO0CON.2 and SIO1CON.2 must be set to "1" to enable the data shifters, respectively.
4. For interrupt generation, set the serial I/O interrupt enable bits (SIO0CON.1, SIO1CON.1) to "1", respectively.
5. When you transmit data to the serial buffer, write data to SIO0DATA or SIO1DATA and set SIO0CON.3 or SIO1CON.3 to 1, the shift operation starts.
6. When the shift operation (transmit/receive) is completed, the SIO0 and SIO1 pending bits (SIO0CON.0 and SIO1CON.0) are set to "1" and SIO interrupt requests are generated, respectively.

SIO0 AND SIO1 CONTROL REGISTERS (SIO0CON, SIO1CON)

The control registers for serial I/O interface modules, SIO0CON, is located at E9H and SIO1CON, is located at ECH in set 1, bank 0. They have the control settings for SIO modules, respectively.

- Clock source selection (internal or external) for shift clock
- Interrupt enable
- Edge selection for shift operation
- Clear 3-bit counter and start shift operation
- Shift operation (transmit) enable
- Mode selection (transmit/receive or receive-only)
- Data direction selection (MSB first or LSB first)

A reset clears the SIO0CON and SIO1CON values to "00H". This configures the corresponding modules with an internal clock source at the SCK0 and SCK1, selects receive-only operating mode, and clears the 3-bit counter, respectively. The data shift operation and the interrupt are disabled. The selected data direction is MSB-first.

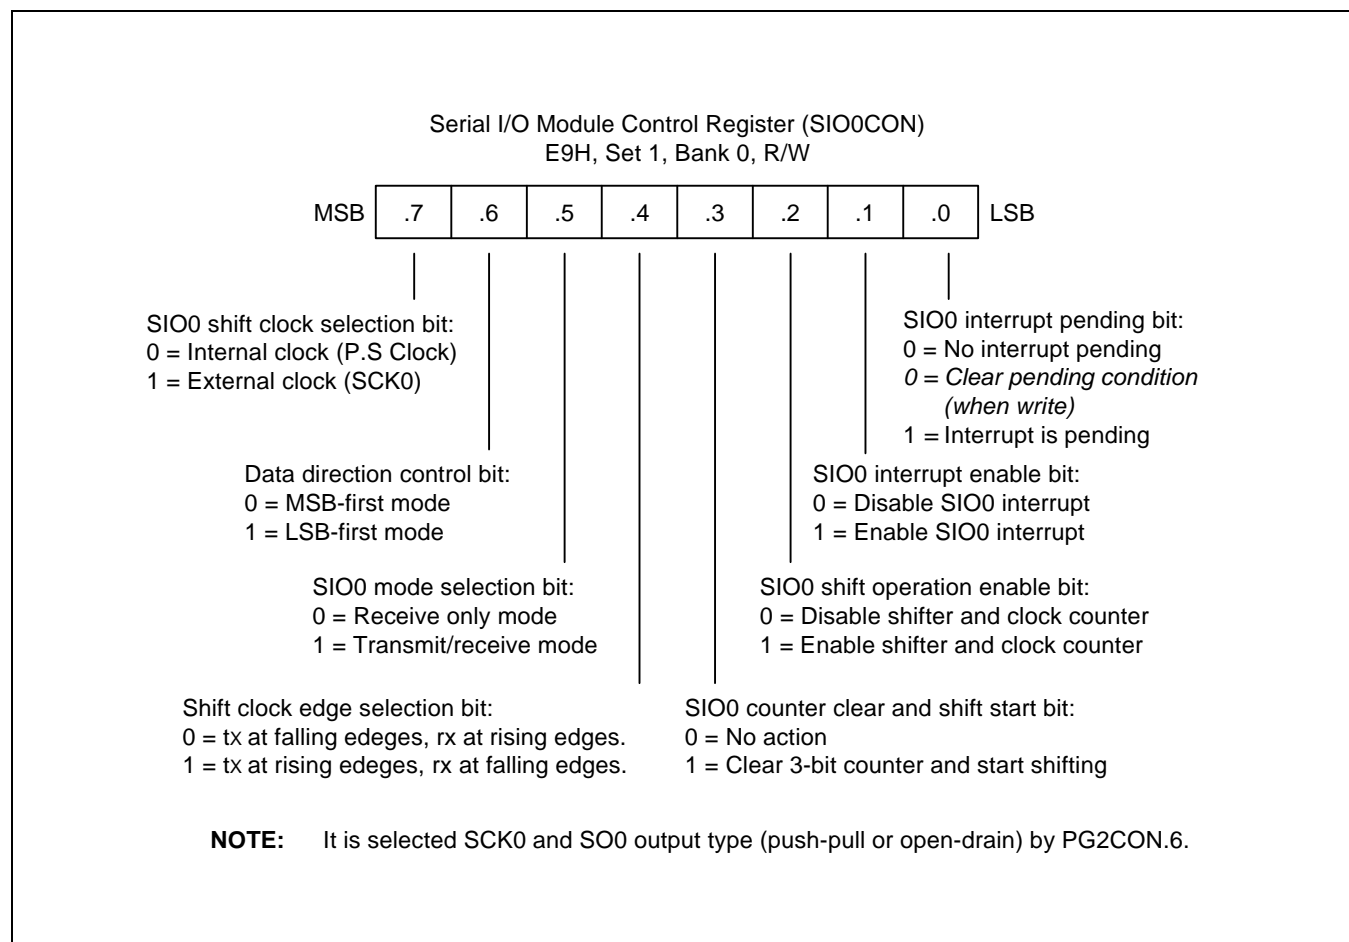

Figure 16-1. Serial I/O Module Control Register (SIO0CON)

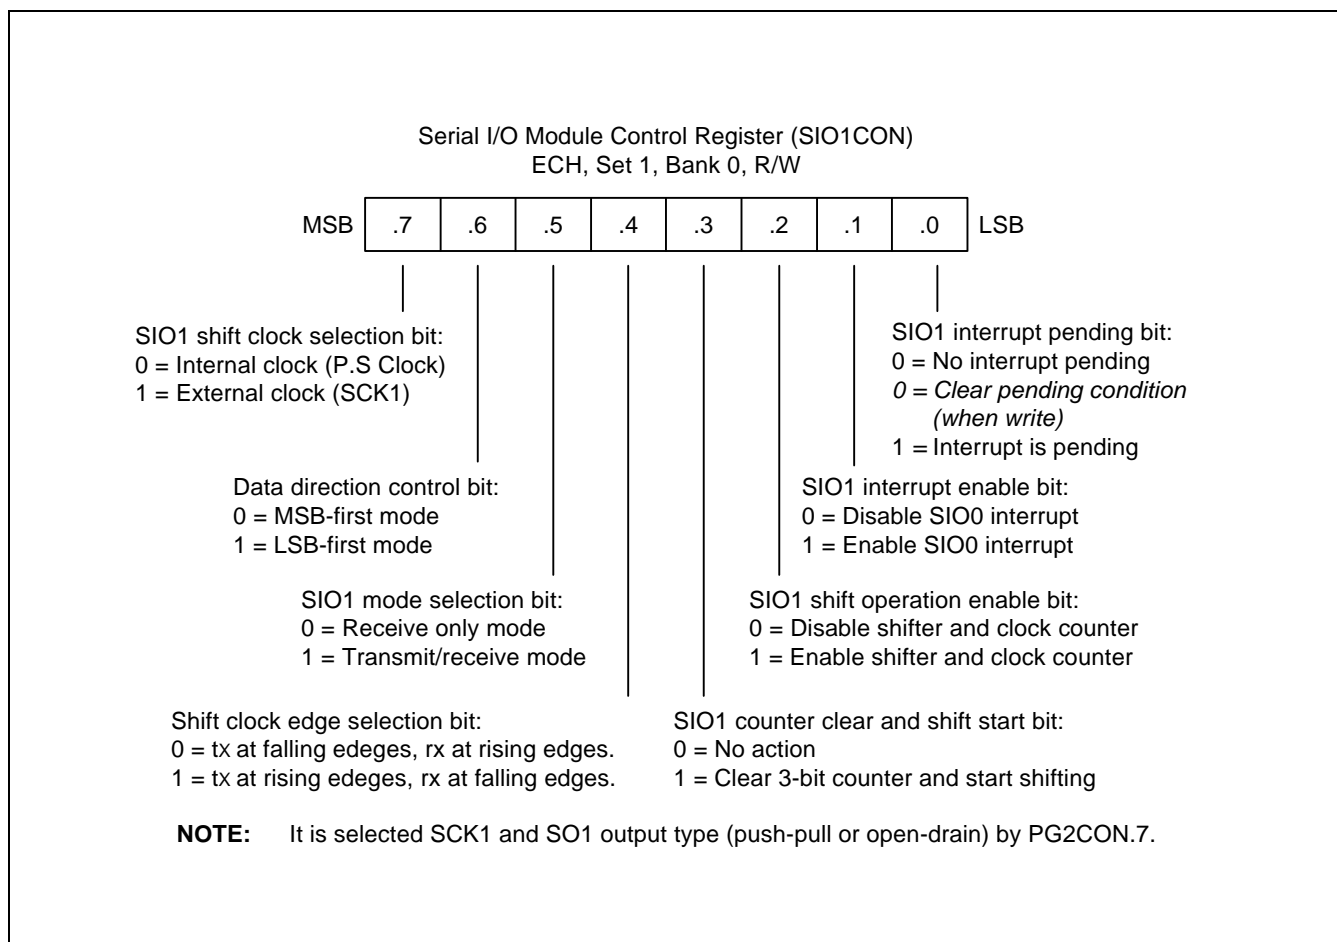

Figure 16-2. Serial I/O Module Control Register (SIO1CON)

SIO0 AND SIO1 PRE-SCALER REGISTER (SIO0PS, SIO1PS)

The prescaler registers for serial I/O interface modules, SIO0PS and SIO1PS, are located at EBH and EEH in set 1, bank 0, respectively.

The values stored in the SIO0 and SIO1 pre-scale registers, SIO0PS and SIO1PS, lets you determine the SIO0 and SIO1 clock rate (baud rate) as follows, respectively:

Baud rate = Input clock (fxx/4)/(Pre-scaler value + 1), or SCK0 and SCK1 input clock.

LOW VOLTAGE RESET

OVERVIEW

The low voltage reset block is useful for an system reset under the specific voltage of system. The components of LVR block are:

- LVREN pin
- LVRSEL pin
- Reference voltage generator
- Voltage divider
- Comparator
- Glitch filter

LVREN PIN

A LVREN pin is used to enable or disable LVR function.

The LVR function is disabled when the LVREN pin is connected to V_{SS} and is enabled when the LVREN pin is connected to V_{DD} .

LVRSEL PIN

A LVRSEL pin is used to select the criterion voltage of Low Voltage reset. The criterion voltage is typical 3.7V for LVR when the pin is connected to V_{SS} and is typical 2.4V for LVR when the pin is connected to V_{DD} .

PLL FREQUENCY SYNTHESIZER

OVERVIEW

The phase locked loop (PLL) frequency synthesizer locks medium frequency (MF), high frequency (HF), and very high frequency (VHF) signals to a fixed frequency using a phase difference comparison system. As shown in Figure 18-1, the PLL frequency synthesizer consists of an input selection circuit, programmable divider, phase detector, reference frequency generator, and a charge pump.

Figure 18-1. Block Diagram of the PLL Frequency Synthesizer

PLL FREQUENCY SYNTHESIZER FUNCTION

The PLL frequency synthesizer divides the signal frequency at the V_{COAM} or V_{COFM} pin using the programmable divider. It then outputs the phase difference between the divided frequency and reference frequency at the EO0 and EO1 pin.

NOTE

The PLL frequency synthesizer operates only when the CE pin is High level. When the CE pin is Low level, the synthesizer is disable.

Input Selection Circuit

The input selection circuit consists of the V_{COAM} pin and V_{COFM} pins, an FM/AM selector, and two amplifiers. The input selection circuit selects the frequency division method and the input pin of the PLL frequency.

You can choose one of two frequency division methods using the PLL mode register: 1) direct frequency division method, or 2) pulse swallow method. The PLL mode register is also used to select the V_{COAM} or V_{COFM} pin as the frequency input pin.

Programmable Divider

The programmable divider divides the frequency of the signal from the V_{COAM} and V_{COFM} pins in accordance with the values contained in the swallow counter and programmable counter. The programmable divider consists of prescalers, a swallow counter, and a programmable counter.

When the PLL operation starts, the contents of the PLL data registers (PLLD0–PLLD1) and the NF bit in the PLLMOD register are automatically loaded into the 12-bit programmable counter and the 5-bit swallow counter.

When the 12-bit programmable down counter reaches zero, the contents of the data register are automatically reloaded into the programmable counter and the swallow counter for the next counting operation.

If you modify the data register value while the PLL is operating, the new values are not immediately loaded into the two counters; the new data are loaded into the two counters when the current count operation has been completed.

The contents of the data register undetermined after initial power-on. However, the data register retains its current value when the reset operation is initiated by an external reset or a change in level at the CE pin.

The swallow counter is a 5-bit binary down counter; the programmable counter is a 12-bit binary down counter. The swallow counter is for FM mode only. The swallow counter and programmable counter start counting down simultaneously. When the swallow counter starts counting down, the 1/33 prescaler is selected. When the swallow counter reaches zero, it stop operation and selects the 1/32 prescaler.

PLL DATA REGISTER (PLLD)

The frequency division value of the swallow counter and programmable counter is set in the PLL data register (PLLD0-PLLD1). PLL data register configuration is shown in Figure 18-2.

Figure 18-2. PLL Register Configuration

Direct Frequency Division and Pulse Swallow Formulas

In the direct frequency division method, the upper 12 bits are valid. In the pulse swallow method, all 16 bits are valid. The upper 12 bits are set in the programmable counter and the lower 4 bits and the NF bit are set in the swallow counter. The frequency division formulas for both methods, as set in the PLL data register, are shown below:

— Direct frequency division (AM) is

$$f_R = \frac{fV_{COAM}}{N} \text{ (When PLLMOD.7 and PLLMOD.4 are set to logic "00".)}$$

$$f_R = \frac{fV_{COAM}}{8 \times N} \text{ (When PLLMOD.7 and PLLMOD.4 are set to logic "01".)}$$

Where the frequency division value (N) is 12 bits; fV_{COAM} = input frequency at the V_{COAM} pin

— Pulse swallow system is

$$(AM) f_R = \frac{fV_{COAM}}{(N \times 32 + M)} \text{ (When PLLMOD.7 and PLLMOD.4 are set to logic "10".)}$$

$$(FM) f_R = \frac{fV_{COFM}}{(N \times 32 + M)} \text{ (When PLLMOD.7 and PLLMOD.4 are set to logic "11".)}$$

where the frequency division values (N and M) are 12 bits and 5 bits, respectively; fV_{COFM} = input frequency at the V_{COFM} pin.

REFERENCE FREQUENCY GENERATOR

The reference frequency generator produce reference frequency which are then compared by the phase comparator. As shown in Figure 18-3, the reference frequency generator divides a crystal oscillation frequency of 4.5 MHz and generates the reference frequency (f_R) for the PLL frequency synthesizer. Using the PLLREF register, you can select from ten different reference frequencies.

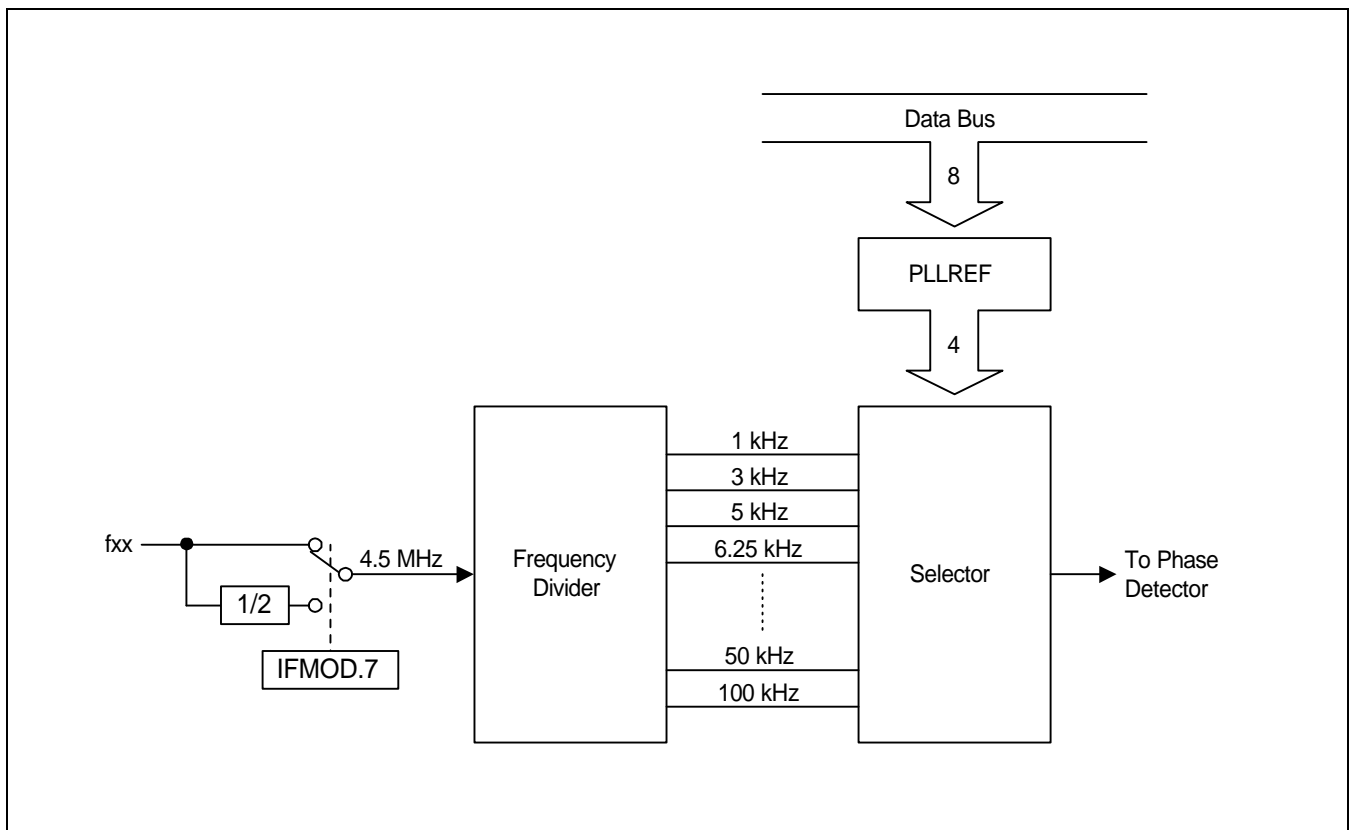

Figure 18-3. Reference Frequency Generator

PLL MODE REGISTER (PLLMOD)

The PLL mode register (PLLMOD) is used to start and stop PLL operation and to enable or disable 3-bit counter for F_{VCOAM} . PLLMOD values also determine the frequency dividing method.

PLLMOD	PLLMOD.7	PLLMOD.6	NF	PLLMOD.4	PLLMOD.3	PLLMOD.2	PLLMOD.1	PLLMOD.0
--------	----------	----------	----	----------	----------	----------	----------	----------

PLLMOD.7 selects the frequency dividing method. The basic configuration for the two frequency dividing methods are as follows:

Direct Method

- Used for AM mode
- Swallow counter is not used
- V_{COAM} pin is selected for input
- Selectable 3-bit counter (PLLMOD.7 and .4)

Pulse Swallow Method

- Used for AM, FM mode
- Swallow counter is used
- V_{COFM} pin is selected for input

The input frequency at the V_{COAM} or V_{COFM} pin is divided by the programmable divider. The frequency division value of the programmable divider is written to the PLL data register.

When the pulse swallow method is selected by setting PLLMOD.7 and PLLMOD.4, the input signal is first divided by a 1/32 or 1/33 prescaler and the divided frequency is input to the programmable divider. Table 18-1 shows PLLMOD organization.

Table 18-1. PLLMOD Organization

PLL Enable and INTIF/INTCE Interrupt Control Bits

PLLMOD.6	0	Disable PLL.
	1	Enable PLL.
PLLMOD.3	0	Disable INTIF interrupt.
	1	Enable INTIF interrupt.
PLLMOD.2	0	INTIF interrupt is not pending (when read).; Clear INTIF pending bit (when write).
	1	INTIF interrupt is pending (when read).
PLLMOD.1	0	Disable INTCE interrupt requests at CE pin.
	1	Enable INTCE interrupt requests at CE pin.
PLLMOD.0	0	INTCE interrupt is not pending (when read).; Clear INTCE pending bit (when write).
	1	INTCE interrupt is pending (when read).

Frequency Division Method Selection Bit

PLLMOD.7 and PLLMOD.4	Frequency Division Method	Selected Pin	Input Voltage	Input Frequency	Division Value
0 0	Direct method for AM	V _{COAM} selected; V _{COFM} pulled Low	300mV _{PP}	0.5–30 MHz	16 to (2 ¹⁶ –1)
0 1	Enable 3-bit counter for AM	V _{COAM} selected; V _{COFM} pulled Low	300mV _{PP}	0.5–30 MHz	16 to (2 ¹⁶ –2)
1 0	Pulse swallow method for AM	V _{COAM} selected; V _{COFM} pulled Low	300mV _{PP}	0.5–30 MHz	2 ¹⁰ to (2 ¹⁸ –2)
1 1	Pulse swallow method for FM	V _{COFM} selected; V _{COAM} pulled Low	300mV _{PP}	30–150MHz	2 ¹⁰ to (2 ¹⁸ –2)

NOTE: The NF bit, a one-bit frequency division value, is written to bit 0 in the swallow counter.

PLL REFERENCE FREQUENCY SELECTION REGISTER (PLLREF)

The PLL reference frequency selection register (PLLREF) used to determine the reference frequency. You can select one of ten reference frequencies by setting bits PLLREF.3–PLLREF.0 to the appropriate value.

PLLREF	PLLREF.7	PLLREF.6	PLLREF.5	PLLREF.4	PLLREF.3	PLLREF.2	PLLREF.1	PLLREF.0
--------	----------	----------	----------	----------	----------	----------	----------	----------

You can select one of the reference frequencies by setting bits PLLREF.3–PLLREF.0.

Table 18-2. PLLREF Register Organization (When f_{xx} = 4.5 MHz)

PLLREF.3	PLLREF.2	PLLREF.1	PLLREF.0	Reference Frequency Selection
0	0	0	0	Select 1 kHz as reference frequency
0	0	0	1	Select 3 kHz as reference frequency
0	0	1	0	Select 5 kHz as reference frequency
0	0	1	1	Select 6.25 kHz as reference frequency
0	1	0	0	Select 9 kHz as reference frequency
0	1	0	1	Select 10 kHz as reference frequency
0	1	1	0	Select 12.5 kHz as reference frequency
0	1	1	1	Select 25 kHz as reference frequency
1	0	0	0	Select 50 kHz as reference frequency
1	0	0	1	Select 100 kHz as reference frequency

NOTE: If the main clock is 9MHz, IFMOD.7 should be set to "1".

PHASE DETECTOR, CHARGE PUMP, AND UNLOCK DETECTOR

The phase comparator compares the phase difference between divided frequency (f_N) output from the programmable divider and the reference frequency (f_R) output from the reference frequency generator.

The charge pump outputs the phase comparator's output from error output pins EO0 and EO1. The relation between the error output pin, divided frequency f_N , and reference frequency f_R is shown below:

$f_R > f_N$ = Low level output

$f_R < f_N$ = High level output

$f_R = f_N$ = Floating level

A PLL operation starts when a value is loaded to the PLLMOD register. The PLL unlock flag (ULFG) in the PLL reference register, PLLREF, provides status information regarding the reference frequency and divided frequency.

The unlock detector detects the unlock state of the PLL frequency synthesizer. The unlock flag in the PLLREF register is set to "1" in an unlock state. When ULFG = "0", the PLL locked state is selected.

PLLREF.7-.4

ULFG

CEFG

IFCFG

POFG

F9H at bank 0 of set 1

The ULFG flag is set continuously at a period of reference frequency f_R by the unlock detector. You must therefore read the ULFG flag in the PLLREF register at periods longer than $1/f_R$ of the reference frequency. ULFG is reset wherever it is read.

PLL operation is controlled by the state of the CE (chip enable) pin. The PLL frequency synthesizer is disabled and the error output pin is set to floating state whenever the CE pin is Low. When CE pin is High level, the PLL operates normally.

The chip enable flag in the PLLREF register, CEFG, provides the status of the current level of the CE pin. Whenever the state of the CE pin goes from Low to High, the CEFG flag is set to "1" and a CE reset operation occurs. When the CE pin goes from High to Low, the CEFG flag is cleared to "0" and a CE interrupt is generated.

The power on flag in the PLLREF register, POFG, is set by initiated power-on reset, but it is not set when a reset occurs on the normal operation. The POFG flag is cleared to "0" by writing "0" to POFG flag bit in PLLREF.

USING THE PLL FREQUENCY SYNTHESIZER

This section describes the steps you should follow when using the PLL direct frequency division method and the pulse swallow method. In each case, you must make the following selections in this order:

1. Frequency division method:

Direct frequency division and enable 3-bit counter (AM) or pulse swallow (AM, FM)
2. Input pin:

VCOAM or VCOFM
3. Reference frequency:

f_R
4. Frequency division value:

N

Direct Frequency Division Method

Select the direct frequency division method by writing a “0” to PLLMOD.7 and PLLMOD.4.

The VCOAM pin is configured for input when you select the direct frequency division method.

Select the reference frequency by writing the appropriate values to the PLLREF register.

The frequency division value is

$$N = \frac{fV_{COAM}}{f_R}$$

(When PLLMOD.7 and PLLMOD.4 = 00), $N = \frac{fV_{COAM}}{8 \times f_R}$ (When PLLMOD.7 and PLLMOD.4 = 01)

where fV_{COAM} is the input frequency at the V_{COAM} pin, and f_R is the reference frequency.

Example (When PLLMOD.7 and PLLMOD.4 = 00):

The following data are used to receive an AM-band broadcasting station:

- Receive frequency:

1422 kHz
- Reference frequency:

9 kHz
- Intermediate frequency:

+ 450 kHz

The frequency division value N is calculated as follows:

$$N = \frac{fV_{COAM}}{f_R} = \frac{(1422+450) \times 10^3}{9 \times 10^3} = 208 \text{ (decimal)}$$

= 0D0H (hexadecimal)

You would modify the PLL data register and PLLMOD.7–.4 register as follows:

PLLD1

0000

1101

0

D

0

PLLD0

0000

xxxx

PLMOD.7-.4

01

xx

0

NF

NOTE: In the direct method, the contents of PLLD0.3-PLLD0.0 and NF are not evaluated.

Pulse Swallow Method

1. Select the pulse swallow method by writing a "1" to PLLMOD.7 and PLLMOD.4.
2. The VCOFM pin is configured for input when you select the pulse swallow method.
3. Select the reference frequency by writing the appropriate value to the PLLREF register.
4. Calculate the frequency division value as follows:

$$32N + M = \frac{fV_{\text{COFM}}}{f_R} \text{ (When PLLMOD.7 and PLLMOD.4 = 11),}$$

$$32N + M = \frac{fV_{\text{COAM}}}{f_R} \text{ (When PLLMOD.7 and PLLMOD.4 = 10)}$$

where fV_{COFM} is the input frequency at the V_{COFM} pin, and f_R is the reference frequency, N is the quotient of $\frac{fV_{\text{COFM}}}{32f_R}$ and M is the remainder of $\frac{fV_{\text{COFM}}}{32f_R}$.

Example (When PLLMOD.7 and PLLMOD.4 = 11):

The following data are used to receive an FM-band broadcasting station:

Receive frequency:	100.0 MHz
Reference frequency:	25 kHz
Intermediate frequency:	10.7 MHz

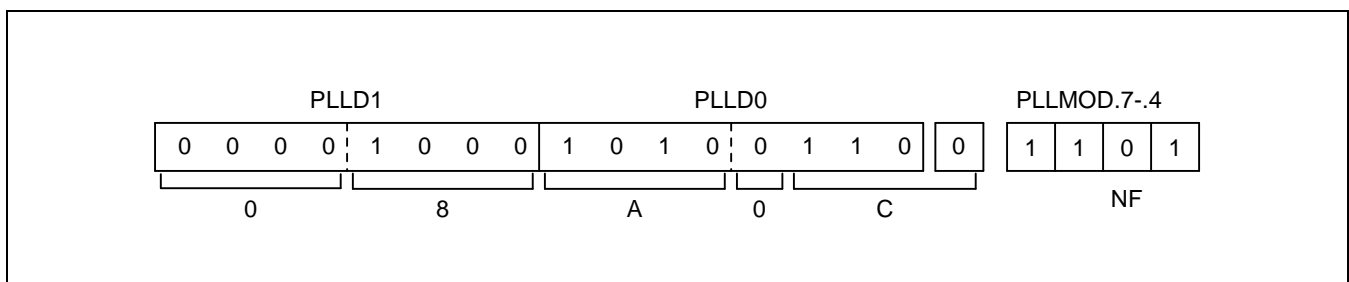

The frequency division value N and M are calculated as follows:

$$\frac{fV_{\text{COFM}}}{f_R} = \frac{(100.0 + 10.7) \times 10^6}{25 \times 10^3} = 4428 = 138 \times 32 + 12$$

$N = 138$ (decimal) = 8AH (hexadecimal)

$M = 12$ (decimal) = 0C (hexadecimal)

You would modify the PLL data register and PLLMOD.7–.4 register as follows:

19

INTERMEDIATE FREQUENCY COUNTER

OVERVIEW

The S3C831B uses an intermediate frequency counter (IFC) to counter the frequency of the AM or FM signal at FMIF or AMIF pin. The IFC block consists of a 1/2 divider, gate control circuit, IFMOD register (IFMOD) and a 16-bit binary counter. The gate control circuit, which controls the frequency counting time, is programmed using the IFMOD register. Four different gate times can be selected using IFMOD register settings.

During gate time, the 16-bit IFC counts the input frequency at the FMIF or AMIF pins. The FMIF or AMIF pin input signal for the 16-bit counter is selected using IFMOD register settings.

The 16-bit binary counter (IFCNT1-IFCNT0) can be read by 8-bit register addressing mode only. When the FMIF pin input signal is selected, the signal is divided by two. When the AMIF pin input signal is directly connected to the IFC, it is not divided.

By setting IFMOD register, the gate is opened for 2-ms, 8-ms, or 16-ms periods. During the open period of the gate, input frequency is counted by the 16-bit counter. When the gate is closed, the counting operation is complete, and an interrupt is generated.

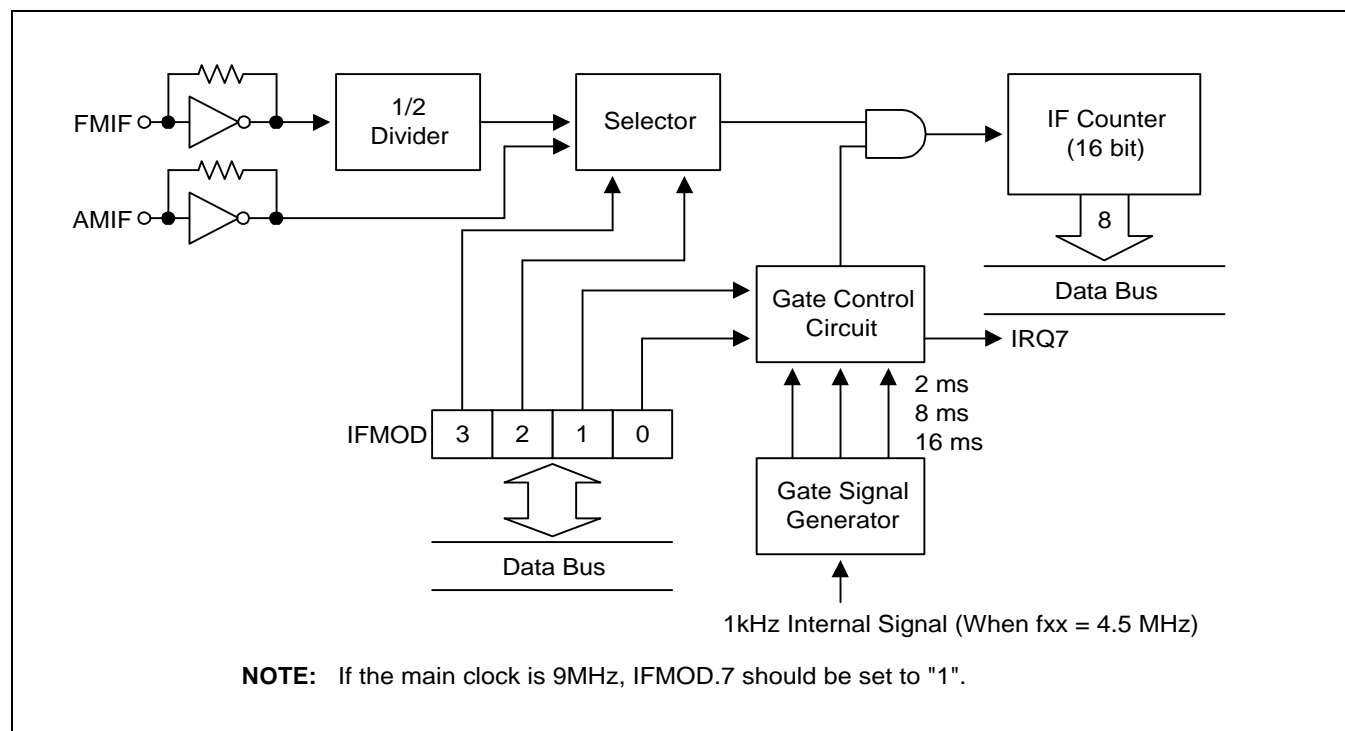

Figure 19-1. IF Counter Block Diagram

IFC MODE REGISTER (IFMOD)

The IFC mode register (IFMOD) is a 8-bit register that is used to select the input pin, divider for V_{COFM} input frequency, PLL/IPC operation voltage, clock divider for PLL/IFC/WT, and gate time. Setting IFMOD register reset IFC value and IFC gate flag value, and starts IFC operation.

IFMOD

IFMOD.7	IFMOD.6	IFMOD.5	IFMOD.4	IFMOD.3	IFMOD.2	IFMOD.1	IFMOD.0
---------	---------	---------	---------	---------	---------	---------	---------

 F3H at bank 0 of set 1

IFC operation starts when you select AMIF or FMIF as the IFC input pin. A reset operation clears all IFMOD values to "0".

Table 19-1. IFMOD Organization

PLL Frequency Synthesizer, If Counter, Watch Timer Clock Control Bit

IFMOD.7	PLL, IFC, Watch Timer Clock Setting
0	The fxx is not divided for PLL/IFC/WT clock.
1	The fxx is divided by 2 for PLL/IFC/WT clock.

The PLL/IFC Operation Voltage Selection Bit

IFMOD.4	Operation Voltage Selection for PLL/IFC
0	Select the PLL/IFC operation voltage as 4.5V to 5.5V
1	Select the PLL/IFC operation voltage as 2.5V to 3.5V

Table 19-1. IFMOD Organization (Continued)

Pin Selection Bits

IFMOD.3	IFMOD.2	Effect of Control Setting
0	0	IFC is disabled; FMIF/AMIF are pulled down and FMIF/AMIF's feed-back resistor are off.
0	1	Enable IFC operation; AMIF pin is selected; FMIF is pulled down and FMIF's feed-back resistor is off.
1	0	Enable IFC operation; FMIF is selected; AMIF is pulled down and AMIF's feed-back resistor is off.
1	1	Enable IFC operation; Both AMIF and FMIF are selected.

Gate Time Select Bits

IFMOD.1	IFMOD.0	Select Gate Time
0	0	Gate time is 2 ms.
0	1	Gate time is 8 ms.
1	0	Gate time is 16 ms.
1	1	Gate is open

IFC GATE FLAG REGISTER (PLLREF.5)

PLLREF.7-4

ULFG	CEFG	IFCFG	POFG
------	------	--------------	------

 F9H at bank 0 of set 1

When IFC operation is started by setting IFMOD, the IFC gate flag (IFCFG) is cleared to "0". After a specified gate time has elapsed, the IFCFG bit is automatically set to "1". This lets you check whether a IFC counting operation has been completed or not.

The IFC interrupt can also be used to check whether or not a IFC counting operation is complete.

GATE TIMES

When you write a value to IFMOD, the IFC gate is opened for a 1-millisecond, 4-millisecond, or 8-millisecond interval, setting with a rising clock edge. When the gate is open, the frequency at the AMIF or FMIF pin is counted by the 16-bit counter. When the gate closes, the IFC gate flag (IFCFG) is set to "1". An interrupt is then generated and the IFC interrupt pending bit (PLLMOD.2) is set.

Figure 19-2 shows gate timings with a 1-kHz internal clock.

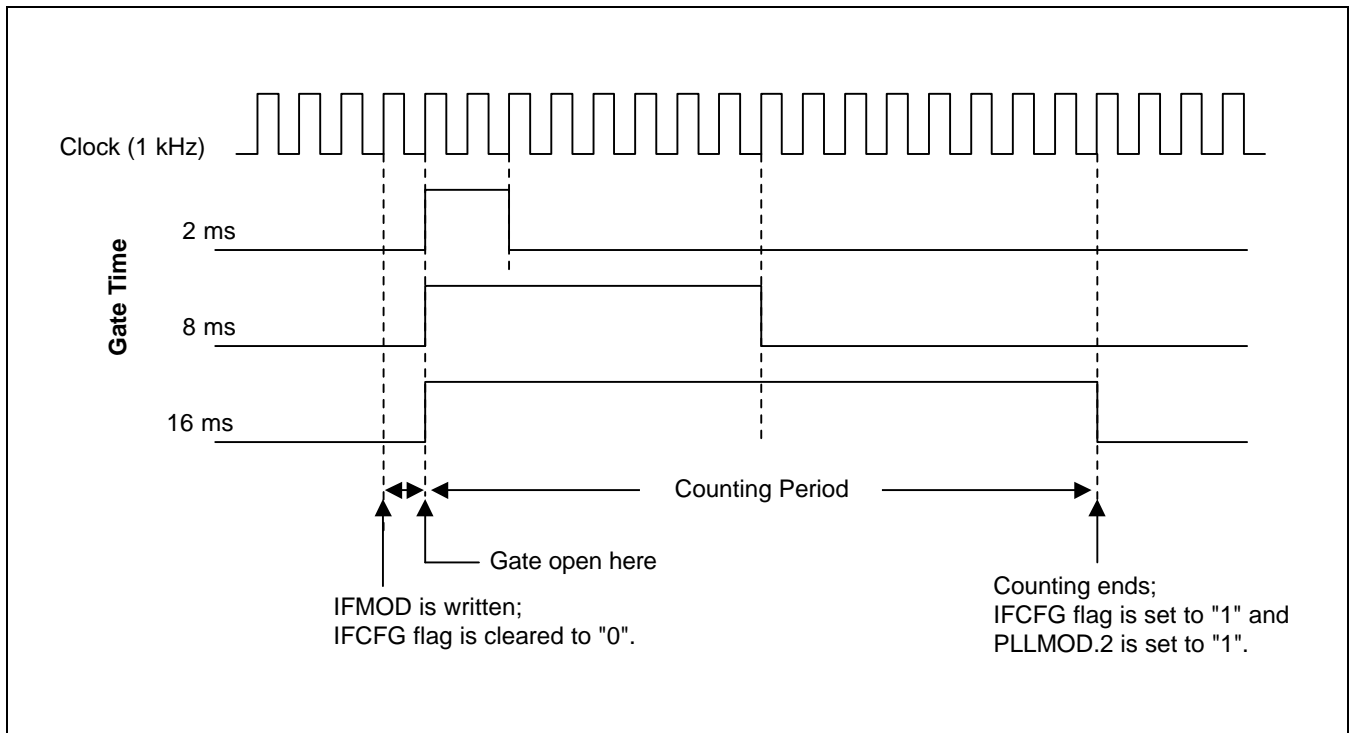

Figure 19-2. Gate Timing (2,8, or 16 ms)

Selecting “Gate Remains Open”

If you select “gate remain open” (IFMOD.0 and IFMOD.1 = “1”), the IFC counts the input signal during the open period of the gate. The gate closes the next time a value is written to IFMOD.

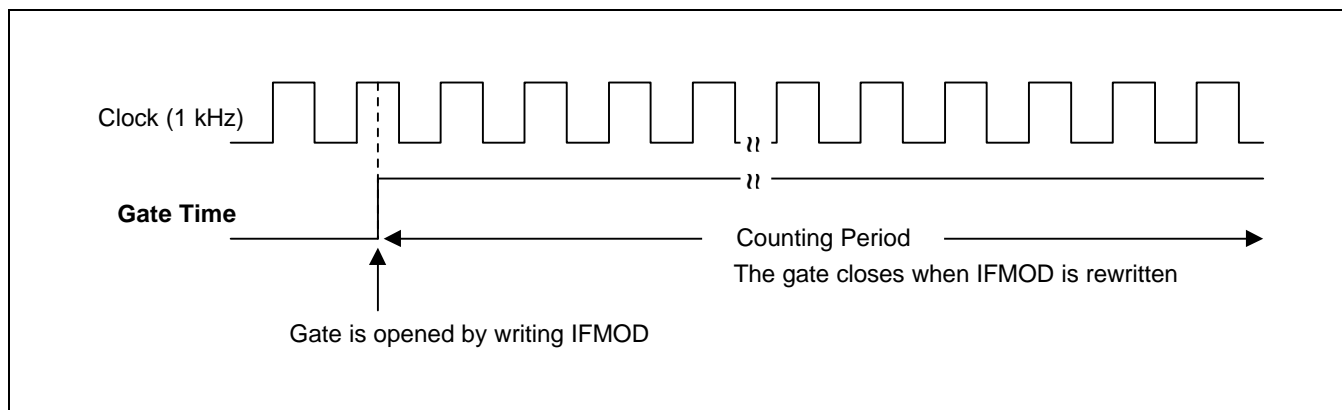

Figure 19-3. Gate Timing (When Open)

When you select “gate remains open” as the gating time, you can control the opening and closing of the gate in one of two ways:

- Set the gate time to a specific interval (2-ms, 8-ms, or 16-ms) by setting bits IFMOD.1 and IFMOD.0.

- Disable IFC operation by clearing bits IFMOD.3 and IFMOD.2 to “0”. This method lets the gate remain open, and stops the counting operation.

Gate Time Errors

A gate time error occurs whenever the gate signals are not synchronized to the interval instruction clock. That is, the IFC does not start counter operation until a rising edge of the gate signal is detected, even though the counter start instruction (setting bits IFMOD.3 and IFMOD.2) has been executed. Therefore, there is a maximum 1-ms timing error (see Figure 19-4).

After you have executed the IFC start instruction, you can check the gate state at any time. Please note, however that the IFC does not actually start its counting operation until stabilization time for the gate control signal has elapsed.

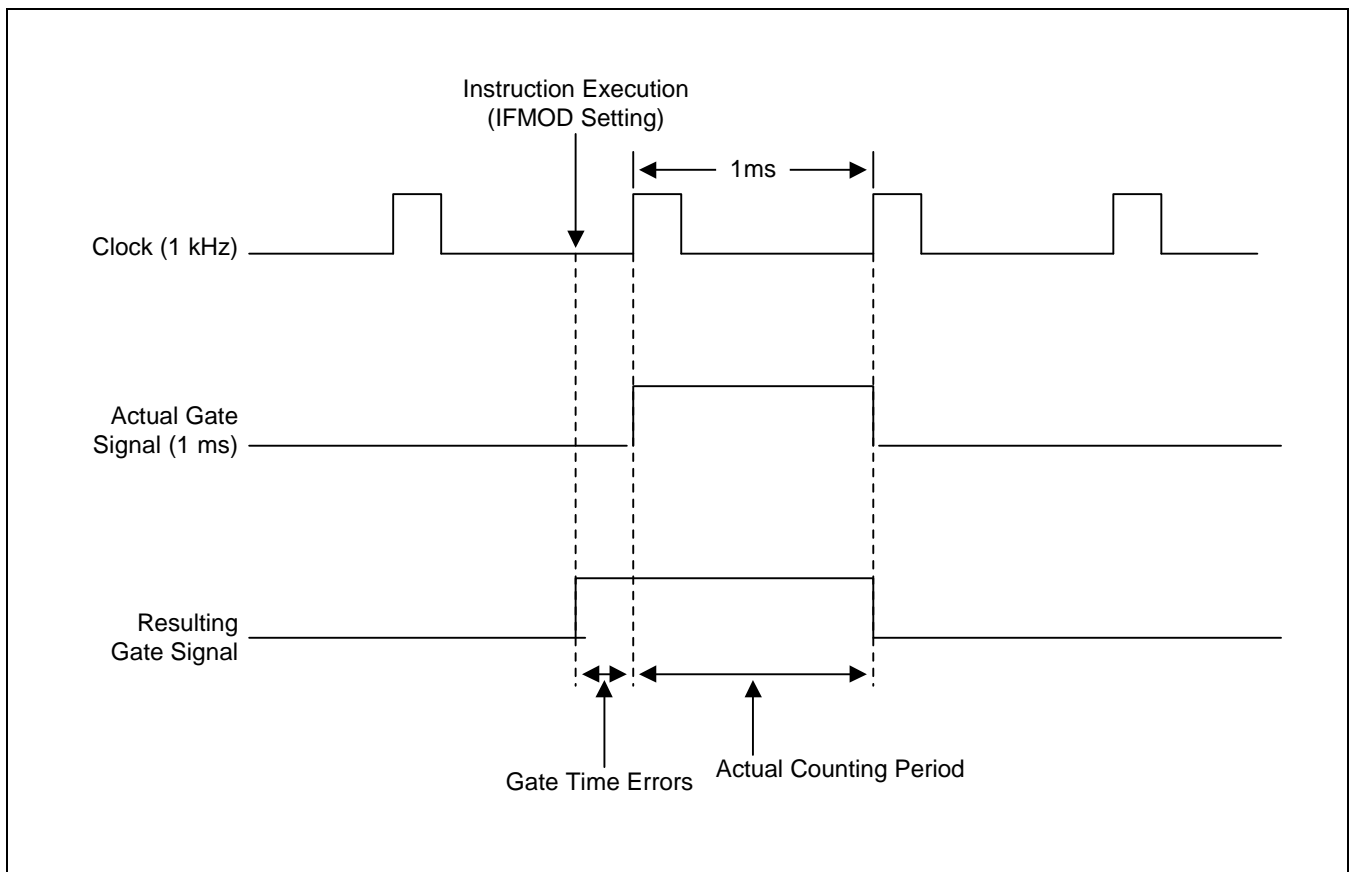

Figure 19-4. Gate Timing (1-ms Error)

Counting Errors

The IF counter counts the rising edges of the input signal in order to determine the frequency. If the input signal is High level when the gate is open, one additional pulse is counted. When the gate is close, however, counting is not affected by the input signal status. In other words, the counting error is "+1, 0".

IF COUNTER (IFC) OPERATION

IFMOD register bits 2 and 3 are used to select the input pin and to start or stop IFC counting operation. You stop the counting operation by clearing IFMOD.2 and IFMOD.3 to “0”. The IFC retains its previous value until IFMOD register values are specified.

Setting bits IFMOD.3 and IFMOD.2 starts the frequency counting operation. Counting continues as long as the gate is open. The 16-bit counter value is automatically cleared to 0000H after it overflows (at FFFFH), and continues counting from zero. The 16-bit count value (IFCNT1-IFCNT0) can be read by register addressing mode. A reset operation clears the counter to zero.

IFCNT0	IFCNT0.7	IFCNT0.6	IFCNT0.5	IFCNT0.4	IFCNT0.3	IFCNT0.2	IFCNT0.1	IFCNT0.0
IFCNT1	IFCNT1.7	IFCNT1.6	IFCNT1.5	IFCNT1.4	IFCNT1.3	IFCNT1.2	IFCNT1.1	IFCNT1.0

When the specified gate open time has elapsed, the gate closes in order to complete the counter operation. At this time, the IFC interrupt pending bit (PLLMOD.2) is automatically set to “1” and an interrupt is generated. The pending bit must be cleared to “0” by software when the interrupt is serviced. The IFC gate flag (IFCFG) is set to “1” at the same time the gate is closed. Since the IFCFG flag is cleared to “0” when IFC operation start, you can check the IFCFG flag to determine when IFC operation stops (that is, when the specified gate open time has elapsed).

The frequency applied to FMIF or AMIF pin is counted while the gate is open. The frequency applied to FMIF pin is divided by 2 before counting. The relationship between the count value (N) and input frequencies f_{AMIF} and f_{FMIF} is shown below.

— FMIF pin input frequency is

$$f_{FMIF} = \frac{N (DEC)}{T_G} \times 2$$

when T_G = gate time (2 ms, 8 ms, 16 ms)

— AMIF pin input frequency is

$$f_{AMIF} = \frac{N (DEC)}{T_G}$$

when T_G = gate time (2 ms, 8 ms, 16 ms)

Table 19-2 shows the range of frequency that you can apply to the AMIF and FMIF pins.

Table 19-2. IF Counter Frequency Characteristics

Pin	Voltage Level	Frequency Range
AMIF	300 m V_{PP} (min)	0.1 MHz to 1 MHz
FMIF	300 m V_{PP} (min)	5 MHz to 15 MHz

INPUT PIN CONFIGURATION

The AMIF and FMIF pins have built-in AC amplifiers (see Figure 19-5). The DC component of the input signal must be stripped off by the external capacitor.

When the AMIF or FMIF pin is selected for the IFC function and the switch is turned on voltage of each pin increases to approximately $1/2 V_{DD}$ after a sufficiently long time. If the pin voltage does not increase to approximately $1/2 V_{DD}$, the AC amplifier exceeds its operating range, possibly causing an IFC malfunction. To prevent this from occurring, you should program a sufficiently long time delay interval before starting the count operation.

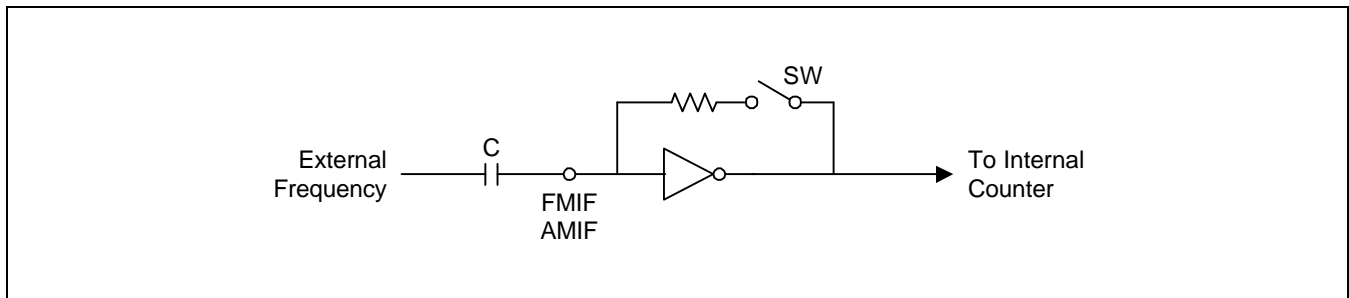

Figure 19-5. AMIF and FMIF Pin Configuration

IFC DATA CALCULATION

Selecting the FMIF pin for IFC Input

First, divide the signal at the FMIF pin by 2, and then apply this value to the IF counter. This means that the IF counter value is equal to one-half of the input signal frequency.

FMIF input frequency (f_{FMIF}): 10.7 MHz

Gate time (T_G): 8 ms

IFC counter value (N):

$$\begin{aligned} N &= (f_{\text{FMIF}}/2) \times T_G \\ &= 10.7 \times 10^6 / 2 \times 8 \times 10^{-3} \\ &= 42800 \\ &= \text{A730H} \end{aligned}$$

ELECTRICAL DATA

OVERVIEW

In this chapter, S3C831B electrical characteristics are presented in tables and graphs. The information is arranged in the following order:

- Absolute maximum ratings
- D.C. electrical characteristics
- A.C. electrical characteristics
- Input/output capacitance
- Data retention supply voltage in stop mode
- A/D converter electrical characteristics
- PLL electrical characteristics
- Low voltage reset electrical characteristics
- Serial I/O timing characteristics
- Oscillation characteristics
- Oscillation stabilization time

Table 20-1. Absolute Maximum Ratings

(T_A = 25 °C)

Parameter	Symbol	Conditions	Rating	Unit
Supply voltage	V _{DD}	–	– 0.3 to +6.5	V
Input voltage	V _I	Ports 0–8	– 0.3 to V _{DD} + 0.3	
Output voltage	V _O	–	– 0.3 to V _{DD} + 0.3	
Output current high	I _{OH}	One I/O pin active	– 15	mA
		All I/O pins active	– 60	
Output current low	I _{OL}	One I/O pin active	+ 30	
		Total pin current for port	+ 100	
Operating temperature	T _A		– 25 to + 85	°C
Storage temperature	T _{STG}		– 65 to + 150	

Table 20-2. D.C. Electrical Characteristics

(T_A = –25 °C to + 85 °C, V_{DD} = 2.2 V to 5.5 V)

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
Operating Voltage	V _{DD}	fx = 0.4–4.5 MHz	2.2	–	5.5	V
		fx = 4.5–9 MHz	4.0	–	5.5	
		PLL, IFC operating	IFMOD.4 = 0	4.5	–	5.5
			IFMOD.4 = 1	2.5	–	3.5
Input High Voltage	V _{IH1}	P1.4–P1.7, Ports 3, 4, 5	0.7 V _{DD}	–	V _{DD}	V
	V _{IH2}	P1.0–P1.3, Ports 0, 2, 6, 7, 8	0.8 V _{DD}		V _{DD}	
	V _{IH3}	RESET, CE	0.8 V _{DD}		V _{DD}	
	V _{IH4}	X _{IN} , X _{OUT}	V _{DD} –0.1		V _{DD}	
Input Low Voltage	V _{IL1}	P1.4–P1.7, Ports 3, 4, 5	–	–	0.3 V _{DD}	V
	V _{IL2}	P1.0–P1.3, Ports 0, 2, 6, 7, 8			0.2 V _{DD}	
	V _{IL3}	RESET, CE			0.2 V _{DD}	
	V _{IL4}	X _{IN} , X _{OUT}			0.1	
Output High Voltage	V _{OH1}	V _{DD} = 4.5 V to 5.5 V EO0, EO1; I _{OH} = –1 mA	V _{DD} – 2.0		V _{DD}	V
	V _{OH2}	V _{DD} = 4.5 V to 5.5 V Other output ports; I _{OH} = –1 mA	V _{DD} – 1.0	–	V _{DD}	
Output Low Voltage	V _{OL1}	V _{DD} = 4.5 V to 5.5 V EO0, EO1; I _{OL} = 1 mA	–		2.0	V
	V _{OL2}	V _{DD} = 4.5 V to 5.5 V Other output ports; I _{OL} = 10 mA	–	–	2.0	

Table 20-2. D.C. Electrical Characteristics (Continued)

(T_A = -25 °C to + 85 °C, V_{DD} = 2.2 V to 5.5 V)

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
Input High Leakage Current	I _{LIH1}	V _{IN} = V _{DD} All input pins except X _{IN} , X _{OUT}	—	—	3	μA
	I _{LIH2}	V _{IN} = V _{DD} , X _{IN} , X _{OUT}			20	
Input Low Leakage Current	I _{LIL1}	V _{IN} = 0 V All input pins except RESET, X _{IN} , X _{OUT}	—	—	-3	
	I _{LIL2}	V _{IN} = 0 V, X _{IN} , X _{OUT}			-20	
Output High Leakage Current	I _{LOH}	V _{OUT} = V _{DD} All output pins	—	—	3	
Output Low Leakage Current	I _{LOL}	V _{OUT} = 0 V All output pins	—	—	-3	
Pull-Up Resistor	R _{L1}	V _{IN} = 0 V; Port 0–8 T _A = 25 °C	V _{DD} = 5 V	25	47	kΩ
			V _{DD} = 3 V	50	95	
	R _{L2}	V _{IN} = 0 V RESET T _A = 25 °C	V _{DD} = 5 V	150	250	
			V _{DD} = 3 V	200	450	
Pull-Down Resistor	R _D	V _{IN} = V _{DD} , V _{DD} = 5 V VCOFM, VCOAM, AMIF and FMIF, T _A = 25 °C	15	30	45	kΩ
Oscillator Feed Back Resistors	R _{OSC}	V _{DD} = 5 V, T _A = 25 °C X _{IN} = V _{DD} , X _{OUT} = 0 V	300	600	1500	kΩ
LCD Voltage Dividing Resistor	R _{LCD}	T _A = 25 °C	70	100	150	kΩ
V _{LCD} – COMi Voltage Drop (I = 0–3)	V _{DC}	–15 μA per common pin	—	45	120	mV
V _{LCD} – SEGx Voltage Drop (x = 0–39)	V _{DS}	–15 μA per common pin	—	45	120	mV
Middle Output Voltage	V _{LC0}	V _{DD} = 2.7 V to 5.5 V	0.6V _{DD} – 0.2	0.6V _{DD}	0.6V _{DD} + 0.2	V
	V _{LC1}		0.4V _{DD} – 0.2	0.4V _{DD}	0.4V _{DD} + 0.2	
	V _{LC2}		0.2V _{DD} – 0.2	0.2V _{DD}	0.2V _{DD} + 0.2	

Table 20-2. D.C. Electrical Characteristics (Concluded)

(T_A = -25 °C to + 85 °C, V_{DD} = 2.2 V to 5.5 V)

Parameter	Symbol	Conditions	Min.	Typ.	Max.	Unit
Supply current ⁽¹⁾	I _{DD1}	Run mode: 4.5 MHz crystal oscillator CE = V _{DD} , V _{DD} = 5 V ± 10 % Crystal Oscillator C1 = C2 = 22pF	—	12.0	25.0	mA
		9.0 MHz		6.5	15.0	
		4.5 MHz		4.0	9.0	
	I _{DD2}	Run mode: CE = 0 V, V _{DD} = 5 V ± 10 % Crystal Oscillator C1 = C2 = 22pF		5.0	12.0	
		9.0 MHz		2.5	5.5	
		4.5 MHz		1.5	3.5	
	I _{DD3}	Idle mode: CE = 0 V, V _{DD} = 5 V ± 10 % Crystal Oscillator C1 = C2 = 22pF		1.5	4.0	
		9.0 MHz		1.0	2.0	
		4.5 MHz		0.5	1.2	
	I _{DD4} ⁽²⁾	Stop mode (in LVR disable): CE = 0 V, T _A = 25 °C, V _{DD} = 5 V ± 10 %		0.5	3	μA
		V _{DD} = 3 V ± 10 %		0.5	2	

NOTES:

1. Supply current does not include current drawn through internal pull-up resistors, PWM, or external output current loads.
2. I_{DD4} is current when the main clock oscillation stops.
3. Every values in this table is measured when bits 4–3 of the system clock control register (CLKCON.4–.3) is set to 11B.

Table 20-3. A.C. Electrical Characteristics

($T_A = -25\text{ }^{\circ}\text{C}$ to $+85\text{ }^{\circ}\text{C}$, $V_{DD} = 2.2\text{ V}$ to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Interrupt input high, low width (P1.0–P1.7)	tINTH, tINTL	P1.0–P1.7, $V_{DD} = 5\text{ V}$	10	–		μs
RESET input low width	tRSL	$V_{DD} = 5\text{ V}$	10	–	–	us

Figure 20-2. Input Timing for RESET

Table 20-4. Input/Output Capacitance

(T_A = -25 °C to +85 °C, V_{DD} = 0 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Input capacitance	C _{IN}	f = 1 MHz; unmeasured pins are returned to V _{SS}	—	—	10	pF
Output capacitance	C _{OUT}					
I/O capacitance	C _{IO}					

Table 20-5. Data Retention Supply Voltage in Stop Mode

(T_A = -25 °C to +85 °C)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Data retention supply voltage	V _{DDDR}		2.2	—	5.5	V
Data retention supply current	I _{DDDR}	V _{DDDR} = 2.2 V (T _A = 25 °C) Stop mode (in LVR disable)	—	—	1	uA

Figure 20-3. Stop Mode Release Timing Initiated by RESET

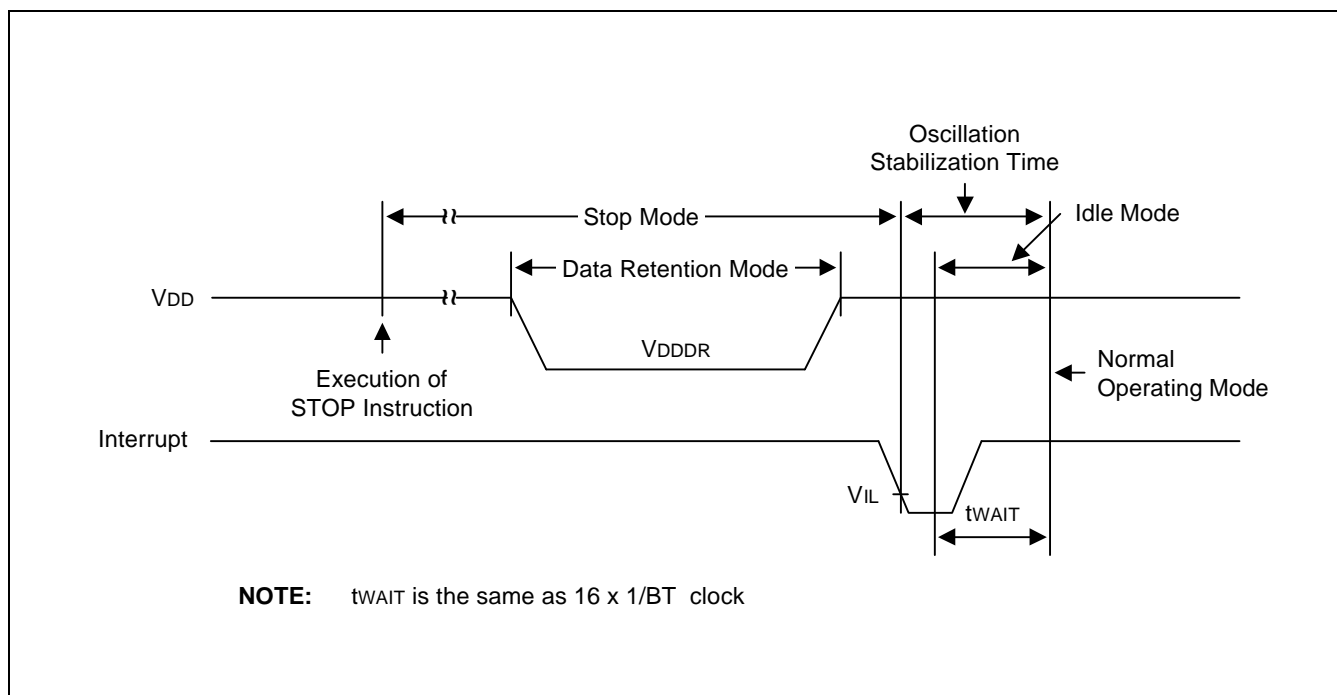

Figure 20-4. Stop Mode Release Timing Initiated by Interrupts

Table 20-6. A/D Converter Electrical Characteristics

($T_A = -25\text{ }^{\circ}\text{C}$ to $+85\text{ }^{\circ}\text{C}$, $V_{DD} = 2.7\text{ V}$ to 5.5 V , $V_{SS} = 0\text{ V}$)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
A/D converting resolution	—	—	—	8	—	bits
Absolute accuracy	—	$V_{DD} = 5.12\text{ V}$	—	—	± 2	LSB
A/D conversion time (NOTE)	t_{CON}	Conversion clock = fxx	$50/fxx$	—	—	μs
Analog input voltage	V_{IAN}	—	V_{SS}	—	V_{DD}	V
Analog input impedance	R_{AN}	$V_{DD} = 5\text{ V}$	2	1000	—	$\text{M}\Omega$

NOTE: A/D Converter needs at least $25\mu\text{s}$ for conversion time.

Table 20-7. PLL Electrical Characteristics

(T_A = -25 °C to +85 °C, V_{DD} = 2.5 V to 3.5 V, 4.5 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
VCOFM, VCOAM, FMIF and AMIF input voltage (peak to peak)	V _{IN}	Sine wave input	0.3	—	V _{DD}	V
Frequency	fV _{COAM}	VCOAM mode, sine wave input; V _{IN} = 0.3V _{P-P}	0.5	—	30	MHz
	fV _{COFM}	VCOFM mode, sine wave input; V _{IN} = 0.3V _{P-P}	30		150	
	f _{AMIF}	AMIF mode, sine wave input; V _{IN} = 0.3V _{P-P}	0.1		1.0	
	f _{FMIF}	FMIF mode, sine wave input; V _{IN} = 0.3V _{P-P}	5		15	

Table 20-8. Low Voltage Reset Electrical Characteristics

(T_A = -25 °C to +85 °C)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
Detect voltage range	V _{DET}	LVRSEL = V _{SS}	3.2	3.7	4.2	V
		LVRSEL = V _{DD}	2.2	2.4	2.7	V
LVR operating current	I _{LVR}	—	—	10	25	μA

Table 20-9. Synchronous SIO Electrical Characteristics

(T_A = -25 °C to +85 °C, V_{DD} = 2.2 V to 5.5 V)

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
SCK0/SCK1 cycle time	t _{CKY}	External SCK0/SCK1 source	1000	—	—	ns
		Internal SCK0/SCK1 source	1000			
SCK0/SCK1 high, low width	t _{KH} , t _{KL}	External SCK0/SCK1 source	500	—	—	
		Internal SCK0/SCK1 source	t _{CKY} /2-50			
SI setup time to SCK0/SCK1 high	t _{SIK}	External SCK0/SCK1 source	250	—	—	
		Internal SCK0/SCK1 source	250			
SI hold time to SCK0/SCK1 high	t _{KSI}	External SCK0/SCK1 source	400	—	—	
		Internal SCK0/SCK1 source	400			
Output delay for SCK0/SCK1 to SO	t _{KSO}	External SCK0/SCK1 source	—	—	300	
		Internal SCK0/SCK1 source	—		250	

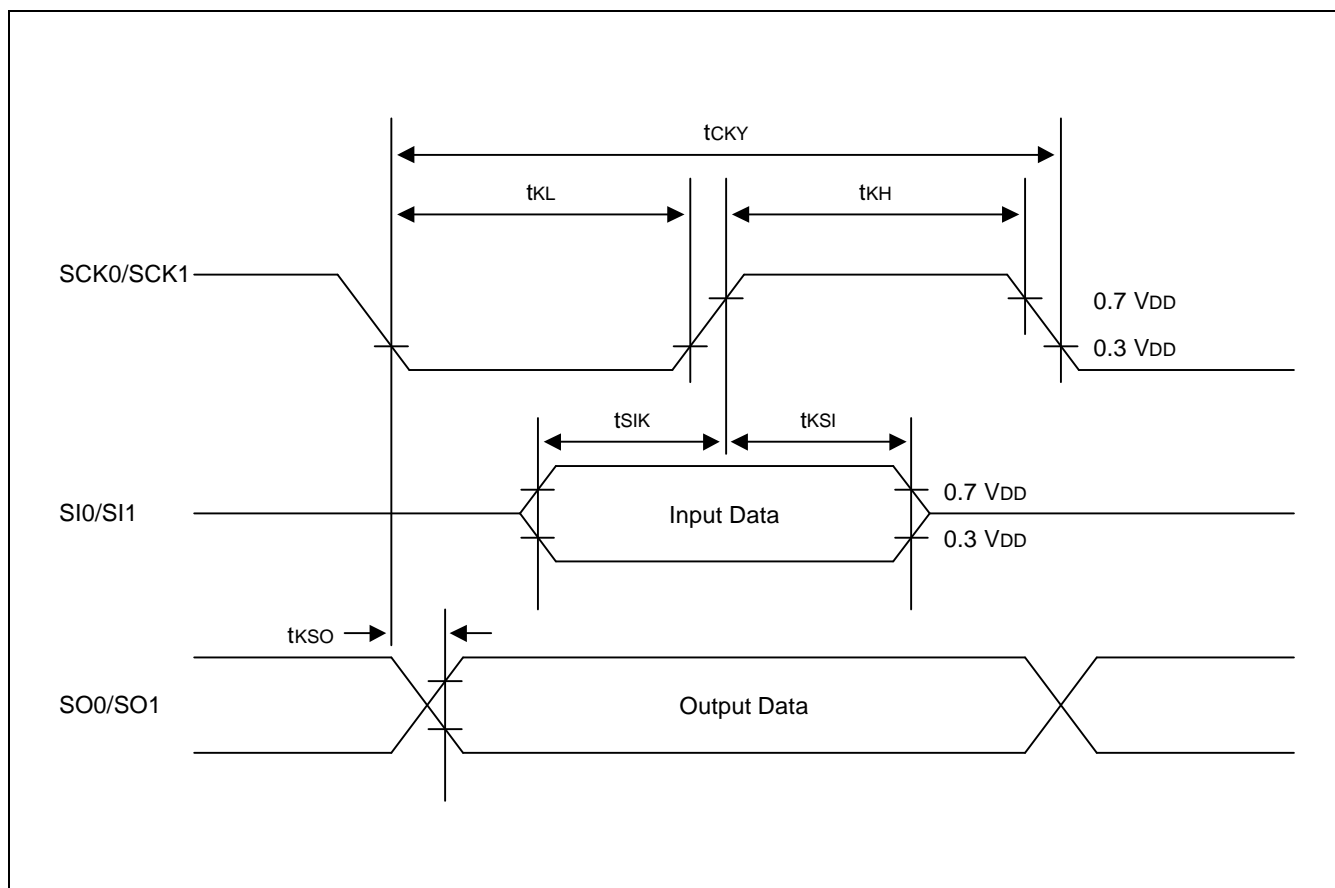

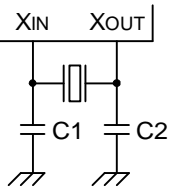

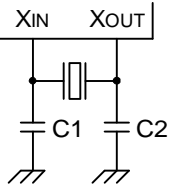

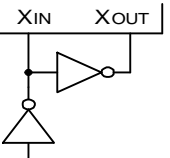

Figure 20-5. Serial Data Transfer Timing

Table 20-10. Main Oscillator Characteristics (fx)

(T_A = -25 °C to +85 °C, V_{DD} = 2.2 V to 5.5 V)

Oscillator	Clock Circuit	Parameter	Test Condition	Min	Typ	Max	Unit
Crystal		Crystal oscillation frequency ⁽¹⁾	V _{DD} = 2.2V – 5.5V	0.4	–	4.5	MHz
			V _{DD} = 4.0V – 5.5V	0.4	–	9	
		Stabilization time ⁽²⁾	Stabilization occurs when V _{DD} is equal to the minimum oscillator voltage range.	–	–	40	ms
Ceramic		Crystal oscillation frequency ⁽¹⁾	V _{DD} = 2.2V – 5.5V	0.4	–	4.5	MHz
			V _{DD} = 4.0V – 5.5V	0.4	–	9	
		Stabilization time ⁽²⁾	–	–	–	10	ms
External Clock		X _{IN} input frequency ⁽¹⁾	V _{DD} = 2.2V – 5.5V	0.4	–	4.5	MHz
			V _{DD} = 4.0V – 5.5V	0.4	–	9	
		X _{IN} input high and low level width (t _{XH} , t _{XL})	V _{DD} = 2.2V – 5.5V	110	–	1250	ns
			V _{DD} = 4.0V – 5.5V	55	–	1250	

NOTES:

- Oscillation frequency and X_{IN} input frequency data are for oscillator characteristics only.
- Stabilization time is the interval required for oscillating stabilization after a power-on occurs, or when stop mode is terminated.

Figure 20-7. Operating Voltage Range

NOTES

21 MECHANICAL DATA

OVERVIEW

The S3C831B microcontroller is currently available in 100-pin-QFP or 100-pin-TQFP package.

Figure 21-1. Package Dimensions (100-QFP-1420C)

22

S3P831B OTP

OVERVIEW

The S3P831B single-chip CMOS microcontroller is the OTP (One Time Programmable) version of the S3C831B microcontroller. It has an on-chip OTP ROM instead of a masked ROM. The EPROM is accessed by serial data format.

The S3P831B is fully compatible with the S3C831B, both in function in D.C. electrical characteristics and in pin configuration. Because of its simple programming requirements, the S3P831B is ideal as an evaluation chip for the S3C831B.

Figure 22-1. S3P831B Pin Assignments (100-Pin QFP Package)

Figure 22-2. S3P831B Pin Assignments (100-Pin TQFP Package)

Table 22-1. Descriptions of Pins Used to Read/Write the EPROM

Main Chip Pin Name	During Programming			
	Pin Name	Pin No.	I/O	Function
P3.2/SO0	SDAT	13(11)	I/O	Serial data pin. Output port when reading and input port when writing. Can be assigned as a Input/push-pull output port.
P3.3/SI0	SCLK	14(12)	I	Serial clock pin. Input only pin.
TEST1	V _{PP}	19(17)	I	Power supply pin for EPROM cell writing (indicates that OTP enters into the writing mode). When 12.5 V is applied, OTP is in writing mode and when 5 V is applied, OTP is in reading mode. (Option)
RESET	RESET	22(20)	I	Chip Initialization
V _{DD} /V _{SS}	V _{DD} /V _{SS}	15/16(13/14)	–	Logic power supply pin. VDD should be tied to +5 V during programming.

NOTE: Parentheses indicate pin number for 100-TQFP-1414 package.

Table 22-2. Comparison of S3P831B and S3C831B Features

Characteristic	S3P831B	S3C831B
Program Memory	64-Kbyte EPROM	64-Kbyte mask ROM
Operating Voltage (V _{DD})	2.2 V to 5.5 V	2.2 V to 5.5 V
OTP Programming Mode	V _{DD} = 5 V, V _{PP} (TEST1) = 12.5 V	
Pin Configuration	100 QFP, 100 TQFP	100 QFP, 100 TQFP
EPROM Programmability	User Program 1 time	Programmed at the factory

OPERATING MODE CHARACTERISTICS

When 12.5 V is supplied to the V_{PP} (TEST1) pin of the S3P831B, the EPROM programming mode is entered. The operating mode (read, write, or read protection) is selected according to the input signals to the pins listed in Table 22-3 below.

Table 22-3. Operating Mode Selection Criteria

VDD	VPP (TEST1)	REG/MEM	Address(A15–A0)	R/W	Mode
5 V	5 V	0	0000H	1	EPROM read
	12.5 V	0	0000H	0	EPROM program
	12.5 V	0	0000H	1	EPROM verify
	12.5 V	1	0E3FH	0	EPROM read protection

NOTE: "0" means Low level; "1" means High level.

CPU Clock = $1/4n \times \text{oscillator frequency}$ ($n = 1, 2, 8, 16$)

When PLL/IFC operation, operating voltage range is 2.5 V to 3.5 V or 4.5 V to 5.5 V.

Figure 22-3. Operating Voltage Range

NOTES

23

DEVELOPMENT TOOLS

OVERVIEW

Samsung provides a powerful and easy-to-use development support system in turnkey form. The development support system is configured with a host system, debugging tools, and support software. For the host system, any standard computer that operates with MS-DOS as its operating system can be used. One type of debugging tool including hardware and software is provided: the sophisticated and powerful in-circuit emulator, SMDS2+, for S3C7, S3C9, S3C8 families of microcontrollers. The SMDS2+ is a new and improved version of SMDS2. Samsung also offers support software that includes debugger, assembler, and a program for setting options.

SHINE

Samsung Host Interface for In-Circuit Emulator, SHINE, is a multi-window based debugger for SMDS2+. SHINE provides pull-down and pop-up menus, mouse support, function/hot keys, and context-sensitive hyper-linked help. It has an advanced, multiple-windowed user interface that emphasizes ease of use. Each window can be sized, moved, scrolled, highlighted, added, or removed completely.

SAMA ASSEMBLER

The Samsung Arrangeable Microcontroller (SAM) Assembler, SAMA, is a universal assembler, and generates object code in standard hexadecimal format. Assembled program code includes the object code that is used for ROM data and required SMDS program control data. To assemble programs, SAMA requires a source file and an auxiliary definition (DEF) file with device specific information.

SASM88

The SASM88 is a relocatable assembler for Samsung's S3C8-series microcontrollers. The SASM88 takes a source file containing assembly language statements and translates into a corresponding source code, object code and comments. The SASM88 supports macros and conditional assembly. It runs on the MS-DOS operating system. It produces the relocatable object code only, so the user should link object file. Object files can be linked with other object files and loaded into memory.

HEX2ROM

HEX2ROM file generates ROM code from HEX file which has been produced by assembler. ROM code must be needed to fabricate a microcontroller which has a mask ROM. When generating the ROM code (.OBJ file) by HEX2ROM, the value "FF" is filled into the unused ROM area up to the maximum ROM size of the target device automatically.

TARGET BOARDS

Target boards are available for all S3C8-series microcontrollers. All required target system cables and adapters are included with the device-specific target board.

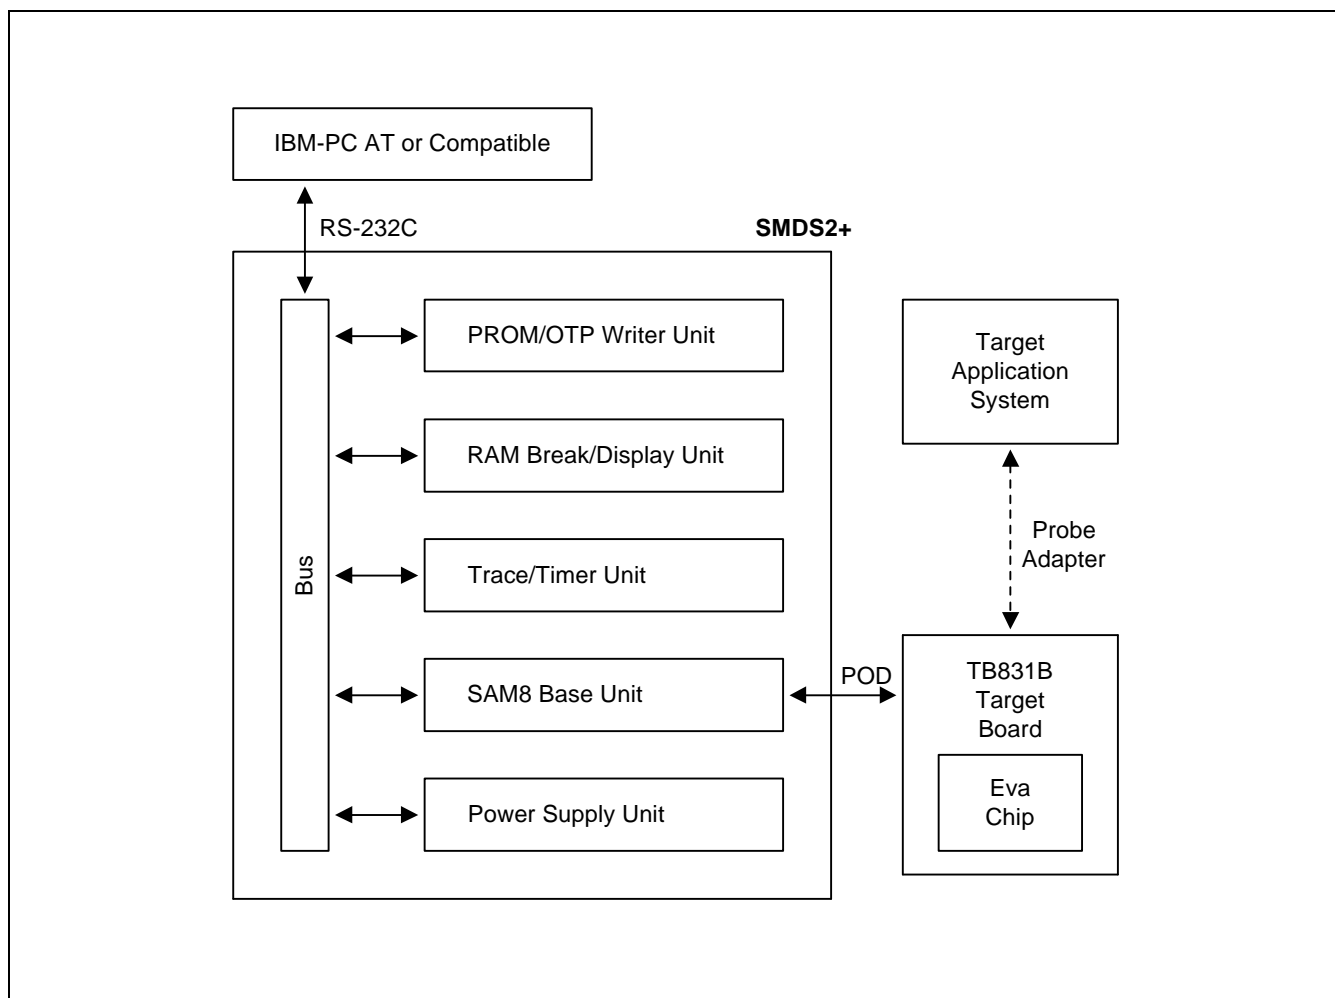

Figure 23-1. SMDS Product Configuration (SMDS2+)

TB831B TARGET BOARD

The TB831B target board is used for the S3C831B/P831B microcontroller. It is supported with the SMDS2+, Smart Kit and OPENice.

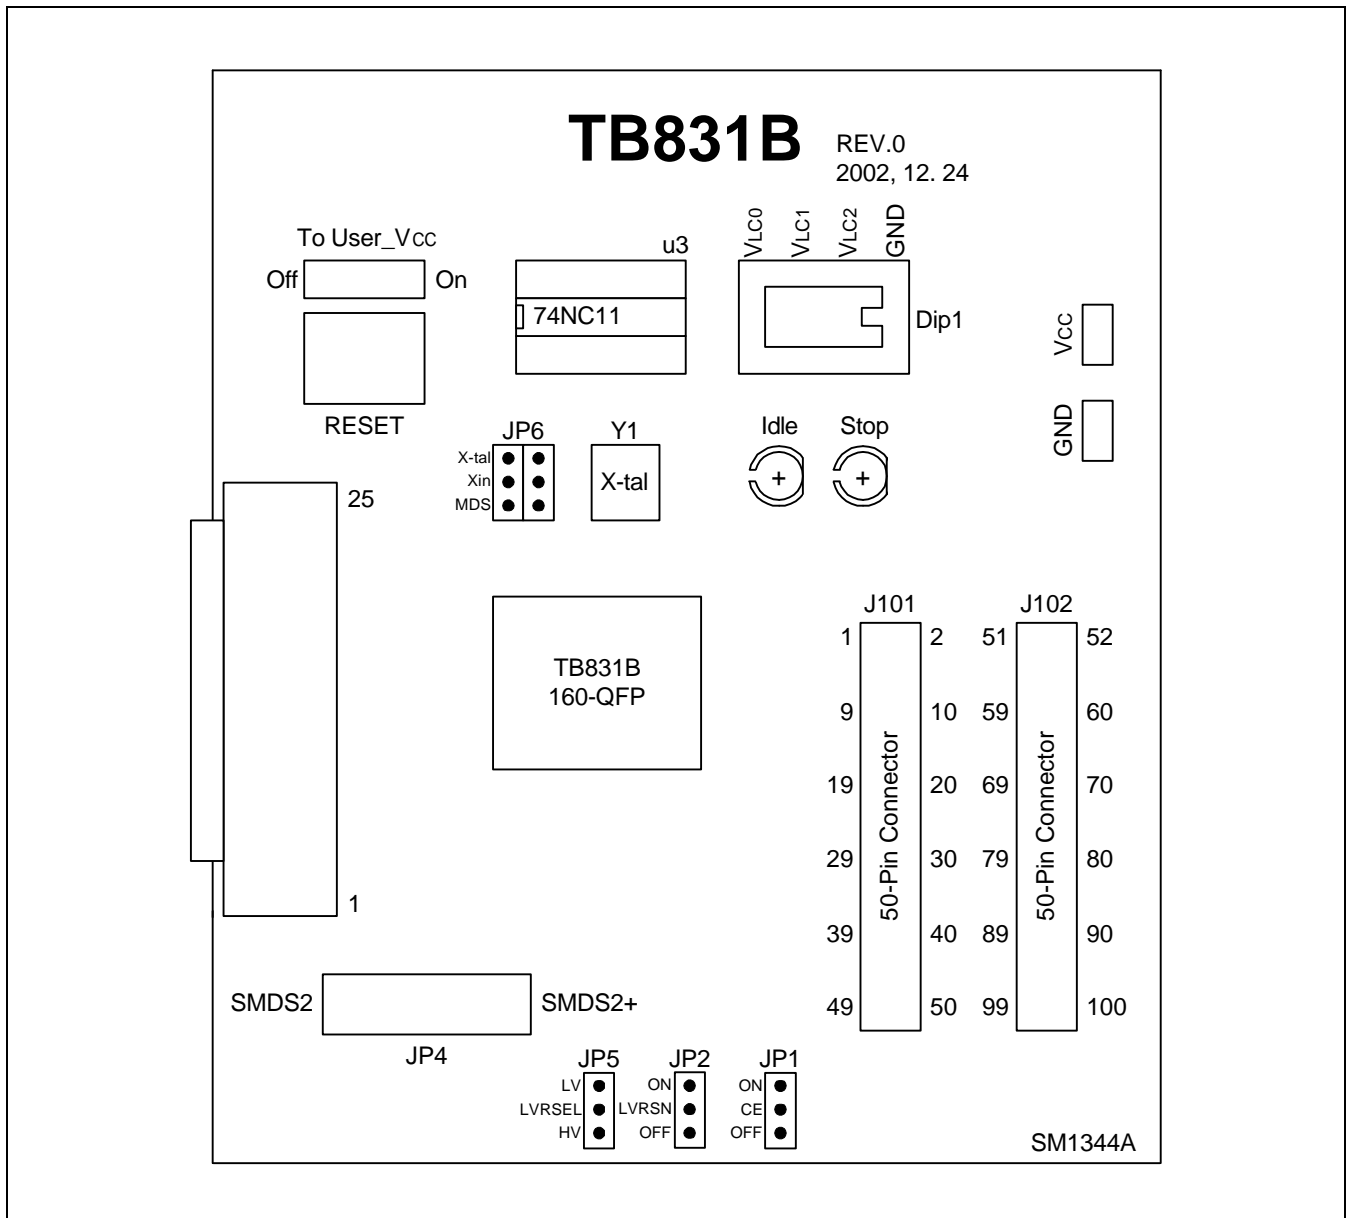

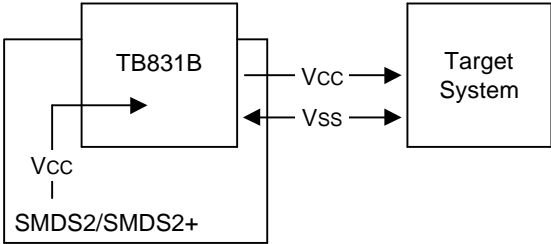

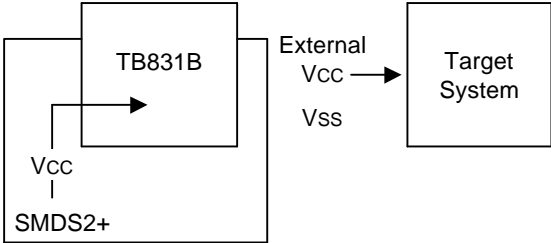

Figure 23-2. TB831B Target Board Configuration

Table 23-1. Power Selection Settings for TB831B

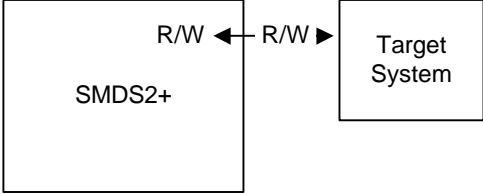

"To User_Vcc" Settings	Operating Mode	Comments
<div>To User_Vcc Off  On</div>		The SMDS2/SMDS2+ supplies V _{CC} to the target board (evaluation chip) and the target system.
<div>To User_Vcc Off  On</div>		The SMDS2/SMDS2+ supplies V _{CC} only to the target board (evaluation chip). The target system must have its own power supply.

NOTE: The following symbol in the "To User_Vcc" Setting column indicates the electrical short (off) configuration:

SMDS2+ SELECTION (SAM8)

In order to write data into program memory that is available in SMDS2+, the target board should be selected to be for SMDS2+ through a switch as follows. Otherwise, the program memory writing function is not available.

Table 23-2. The SMDS2+ Tool Selection Setting

"SW1" Setting	Operating Mode
SMDS2  SMDS2+	

IDLE LED

The Yellow LED is ON when the evaluation chip (S3E8310) is in idle mode.

STOP LED

The Red LED is ON when the evaluation chip (S3E8310) is in stop mode.
