CONTENTS

【Drive Model Naming】

Example: MX-2H 3 04 D /dk

- └ Special series: example, dk for carving machine, GM series without;
- Power Supply type: D for dc power supply, A for 50/60Hz AC power supply (All AC- powered driver can use DC power supply);
- Maximum or typical power supply voltage divided by 10: example for Maximum DC40V power supply. AC supply for virtual value, detail reference to specification instructions;
- Maximum output current: 2-phase drive mark Peak current, 3-phase drive mark value current (RMS), Sample Peak current 3.0A;
- Drive type: 2H for two phase hybrid, 3H for three-phase;
- Drive Series code: MU and EA for micro-drives, MX and TX for min-drive, MZ TZ for medium-drive, TD for large-drives;

【Drive list】

Model	Phase	Segment Step	Output Current	Supply Power & TYPICAL VALUE	Dimensions (mm) Weight(kg)	Size
EA202D	2 phase	2/4/8/16	0.4-1.7A (Max) 4 ranks, accuracy 0.4A	POWER: DC24V POWER OVER 50W	100×60×19 0.17 kg	Micro
MU-2H202D		2/5/10/20/40	1.7A customization, non-adjust			
MX-2H304D	2 phase	22 ranks Max micostep 200 Max step 40000	0.2A-3.0A (Max) 16 ranks, accuracy 0.2A	DC(24-40)V, Typical value DC24、32V POWER OVER 100W	123×76×31 0.27 kg	Min
MX-2H306D				DC(40-60)V, Typical value DC50V POWER OVER 150W	123×76×38 0.35 kg	Min Thicken
TX-2H504D		28 ranks Max step 60000	0.4A-5.0A (Max) 16 ranks, accuracy 0.4A	DC(24-40)V, Typical value DC24/ DC 32V POWER OVER 150W	123×76×31 0.27 kg	Min
TX-3H504D	3 phase	28 ranks Max step 60000	0.3A-5.2A(effective value) 16 ranks, accuracy 0.3A	DC(24-36)V, Typical value DC24 / DC 32V POWER OVER 150W		
MZ-2H504A	2 phase	22 ranks Max step 40000	0.4A-5.0A (Max) 16 ranks, accuracy 0.4A	AC(24-45)V, Typical value AC40V DC(40-60)V, Typical value DC50V POWER OVER 200W	157×99×56 0.7kg	Medium
MZ-2H506A				AC(40-60)V, Typical value AC50V DC(60-80)V, Typical value DC70V POWER OVER 250W		
TZ-2H704A		28 ranks Max step 60000	0.5A-7.5A (Max) 16 ranks, accuracy 0.5A	AC(24-45)V, Typical value AC40V DC(40-60)V, Typical value DC50V POWER OVER 250W		
TZ-3H504A	3 phase	28 ranks Max step 60000	0.3A-5.2A (effective value) 16 ranks, accuracy 0.3A	AC(24-45)V, Typical valuAC40V DC(40-60)V, Typical value DC50V POWER OVER 200W		
TZ-3H506A				AC(40-60)V, Typical value AC50V DC(60-80)V, Typical value DC70V POWER OVER 250W		
TD-2H611A	2 phase	28 ranks Max step 60000	0.4A-6.0A (Max) 16 ranks, accuracy 0.4A	AC(70-140)V, Typical value AC80V & AC110V POWER OVER 500W	177×122×75 1.1kg	large
TD-3H511A	3 phase	28 ranks Max step 60000	0.3A-5.2A (effective value) 16 ranks, accuracy 0.3A	AC(70-140)V, Typical value AC80V & AC110V POWER OVER 500W		
TD-3H522A				AC(180-240)V, Typical value AC220V POWER OVER 600W		

【Drive Operation】

Input power	DC power supply, voltage error -15% - +15%, ripple ≤ 5%; AC power supply, voltage error -30% - +10%, frequency of 50/60Hz
Working condition	Operating temperature: -10°C∼45°C; Humidity: 10∼85% non-condensing; Non-corrosive, explosive, gas or liquid conductive; no metal dust.
Installation	Drive should be installed in a well ventilated and protective electrical control cabinet. Please keep the air channel for the cooling fan drive. If the heat dissipated by drive shell, drive should be fixed in the bigger and thick metal plate or cabinet, contact surface should be smooth or coated with heat conductive silicon grease. Fixing cooling fan beside drive is also a better heat dissipation method.
Connection	Control line should be used to shielded cable and separated with the power line and electrical lines. NOTE: Strictly prohibited tinning on the ending of control line and connection terminals! Otherwise it would cause heat damage to the terminal, generally use lead sheeting or direct access to the drive. PE terminal is ground protection side. In the case of non-isolated powered, drives and motors must be ground protection (Recommended powered by isolation transformer)

【 Driver Connection diagram】
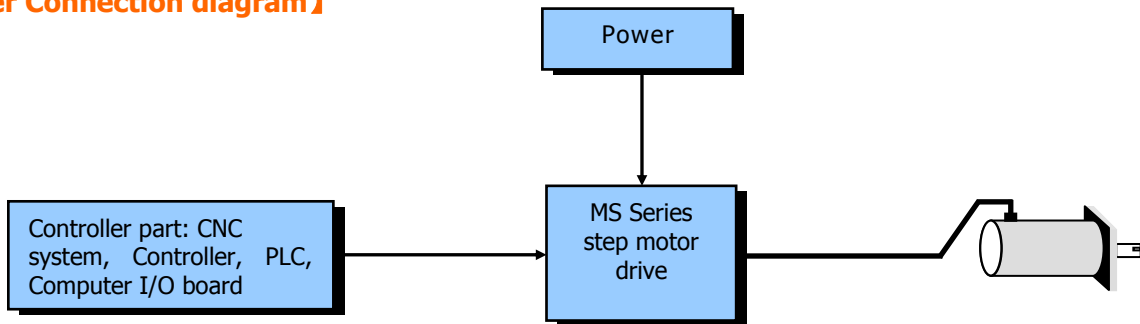

【EA202D and MU-2H202D Drive profile】

EA202D and MU-2H202D step drives are micro-drives; the size and installation are same. The main type used to drive 42 type or small 57 type 2-phase stepper motor. Both of them power supply are DC24, output Max phase current (peak) are 1.7A. The difference is as follows: 1. The number of segments is different (see below); 2. EA202D could set four gear phase current by DIP switch, while the MU-2H202D can only output a fixed current which the user could not adjust, user could customize the current before the instructions, and otherwise the factory default value is 1.7A.

Start Microstep Co., Ltd.

MX-2H304D step drives are mainly used to drive 57 type 2-phase hybrid stepper motor which current is below 3A. It is up to 22 segments and Max 40000 steps. Step could be set by 1 to 5 bit of DIP switch. Signal and doubt pulse mode. Self-test function, Phase memory function, auto half current function. Output max current is 3.0A. Current could be set bye 7 to 10 bit of the DIP switch (it could set 16 speeds current, setting resolution is 0.3A). MX-2H304D step drives is 24V to 49V DC power supply. Typical value is DC 24V or 32V. Recommend using switch power supply, power is over 100W. Relation setting and operation is as shown below.

TZ-3H504A panel drawing

TZ-3H504A step drives are mainly used to drive 86 type 3-phase hybrid stepper motor. It is up to 28 segments and Max 60000 steps. Step could be set by 1 to 5 bit of DIP switch. Signal and doubt pulse mode. Self-test function, Phase memory function, auto half current function. Output max current is 5.2A (effective value). Current could be set bye 7 to 10 bit of the DIP switch (it could set 16 speeds current, setting resolution is 0.3A). TZ-3H504A step drives can drive by DC or AC power. AC input is 24V to 45V. Typical value is AC 40V. DC power is also available, positive and negative can access. DC input is 40V to 60V. Typical value is DC 50V. Supply power is over 200W. Relation setting and operation is as shown below.

TD-3H522A panel drawing

TD-3H522A step drives are mainly used to drive 110 type 3-phase hybrid stepper motor. It is up to 28 segments and Max 60000 steps. Step could be set by 1 to 5 bit of DIP switch. Signal and doubt pulse mode. Self-test function, Phase memory function, auto half current function. Output max current is 5.2A (effective value). Current could be set bye 7 to 10 bit of the DIP switch (it could set 16 speeds current, setting resolution is 0.3A). TD-3H522A step drives can drive by AC. AC input is 180V to 2400V. Typical value is AC 200V and AC220V. Supply power is over 600W. Relation setting and operation is as shown below.

【Drive Main Function Setting & Operation】

Segment Step	EA202D 和 MU-2H202D step drives could be set by 1, 2 bit of DIP switch. EA202D could set 4 segments and MU-2H202D set 5 segments. More detail operation please reference the plant drawing, N/A is invalid condition.
	M series step drives could be set by 1, 2, 3, 4, 5 bit of DIP switch. M series step drives could be set 22 segments (step) and max 40000 steps. Drive should be set before switch on otherwise setting is invalid. More detail operation please reference the plant drawing, N/A is invalid condition.
	T series step drives could be set by 1, 2, 3, 4, 5 bit of DIP switch. M series step drives could be set 28 segments (step) and max 60000 steps. Drive should be set before connect to the power otherwise setting is invalid. More detail operation please reference the plant drawing, N/A is invalid condition.
Signal/doubt pulse setting	EA202D and MU-2H202D step drives only have signal pulse mode. No doubt pulse mode, without setting.
	M and T series step drives have signal pulse mode and doubt pulse mode. Setting 1-5 bit DIP switch as 00000, switch on the driver. After 2 to 5 second the green light twinkling, switch off and then setting the steps and Rpm.
	Doubt pulse setting: Setting 1-5 bit DIP switch as 11111. Switch on the power. After 2 to 5 second the green light twinkling, switch off and then setting the steps and Rpm.
	Notes: Once signal/doubt pulse setting as previous, only when the pulse is change otherwise unnecessary second setting whether drives is switched on or off.
Self-test function	All the step drives have self-test function except EA202D and MU-2H202D. Self-test function: Setting 1-5 bit DIP switch as 11110, switch on the driver. After 2 to 5 second the step drive began in a lower frequency drive motor. This function is used to detect the drives properly without pulse signal setting.
Auto half current function	All models have auto half current function. Drive will automatically enter the half current state after the pulse stop 2 to 5 seconds. The current of the motor is only half of the normally working in order to reduce power consumption and protect the motor. You can also choose without this function (EA202D and MU-2H202D type drive excluded). For the M and T-type drives, the sixth bits DIP switch setting this function: 0 - no such function, 1 - have this function.
Output current setting	EA202D step drive can set 4-speed output current available by setting the DIP switches 3, 4 bit. Data could be read directly from the table. MU-2H202D step drive can not set the output current. Factory-configured by the user, the default value is 1.7A.
	M and T series have 16-speed output current available by setting the DIP switches 7, 8, 9, 10 bit. Drive output sine-wave current to the motor. Current is peak value for 2-phase motor and effective value for 3-phase motor. Total output current is equal to the sum of current when the 7, 8, 9, 10bits switch point 1.
Phase memory function	The drive power-off at a certain phase position, and phase position of next powering up is different, then the motor will chatter look. In order to eliminate chattering of motor, Drive should memory the power off phase position. This function is very important in a certain industries. M and T series have this function, Memory time is infinite. EA202D and MU-2H202D step drive have none.
Signal interface	CP + and CP- are as a step pulse signal positive and negative, DIR + and DIR- are direction level signal positive and negative terminal, EN + and EN- are To enable level signal positive and negative terminal, CW +, and CW- are forward pulse signal positive and negative terminal, CCW + and CCW-is backward pulse signal positive and negative terminal.
Electrical Interface	A, A-, B, B- for connecting 2-phase hybrid motor. Reverse One side of the two phase lines, can reverse the motor; U, V, W for connecting 3-phase hybrid motor. Reverse any two lines, which can make the motor reverse.
Power Interface	Different drives have different power requirements, More details reference relations description in the 【drive list】 & 【Introduction】. Note: All AC-powered drive can be able to driving by DC power.
Indicator	EA202D and MU-2H202D drives only have the power indicator. Other models drive has green and red indicator, respectively indicating the operational status of the drive: Green light, red light off for the normal working condition; green light flash, red light off for setting the single and double pulse; green flash, red light is illegal state; green light, red light flashing for the over current protection state; green light, red double flash for the over-voltage protection; the green light, red light flashes three times for over-temperature protected.
Installation	Considering the heat elimination, drive installation should keep cooling channels

【Driver control signal interface】

Drive is retransmitted weak signal of the computer controller system into strong signal which could be accepted by stepper motor. Control system output three type of driving signal.

1. Step Pulse signal CP: This is the most important signal, because the principle of stepper drive control system is converts the pulse signal of the control system into angular displacement of the stepper motor. Or, Drive receive pulse signal CP, then motor rotate a certain step angle, CP frequency is positive proportional to stepper motor speed. Amount of CP pulse determines the rotation angle of the stepper motor. Thus, control system regulates motor speed and position by CP pulse signal.

2. Direction level signal DIR: This signal defines the motor rotation direction. For example, Motor clockwise rotation in high level signal and anticlockwise rotation in low level signal. This reversing method is called signal pulse mode. In addition, there is a double pulse mode. Drive receive two line pulse signal (marked as CW and CCW). Motor rotates forward in CW pulse signal; motor rotates backward in CCW pulse signal. User setting signal and double pulse by DIP switch.

3. Enable signal EN: No Connection EN signal default effective status, then Drive work. Connect EN signal circuit, drive stop working. Torque free condition (equivalent to FREE signal of SH series drive), this signal is optional signal.

Our driver inner adopt optocoupler isolating input-signal in order to keep the normal communication and avoid mutual interference between the control system and drive. Three-way signal have same inner interface circuit. Common connection is as follows: ① Common-anode mode :Connect CP +, DIR + and EN + as common-anode with +5V external system; Connect pulse signal with CP-; Direction level signal with DIR-; Connect enable signal with EN-; ② Common-cathode mode: Connect CP -, DIR - and EN - as common-cathode with GND external system; Connect pulse signal with CP+; Direction level signal with DIR+; Connect enable signal with EN+; ③ Differential mode: Connect directly.
Drive input signal inner interface diagram

If the drive input signal is voltage signal, voltage range: 3.6V ≤ high level ≤ 5.5V;-5.5V ≤ low level≤ 0.3V, the most commonly is TTL level.

If the drive input signal is current signal, current range: 7mA ≤ high current ≤ 18mA;-18mA ≤ low current ≤ 0.2mA.

Either voltage or current signals, convert into optocoupler input current, in order to transport signal (reference above diagram),

If the voltage signal amplitude exceed standard numerical, user should add limiting resistance on external CP and DIR terminal, to ensure 7-18mA current to the drive's inner optocoupler, reference below diagram.

Signal Amplitude	Limiting Resistance (R)
5V	NON
12V	1.0K
24V	2.0K

Pulse signal control stepper motor running. Stepper motor rotates a certain angle when the effective edge of the stepper motor pulse signal is coming. Effective edge is mean: the moment of pulse signal current from small to large, or the moment of pulse-level from low to high, or the moment of inner drive optocoupler from stop to open.
Pulse frequency requires less than 200 KHz;

Pulse width requirement of not less than 2μS.

Pulse drive current requirements for the 7-18mA

Pulse width≥**2**μS，Pulse frequency≤200KHz   Arbitrary duty ratio

Pulse-level =high

Pulse-level =low
Effective edge

Be sure the motor stopped, and then convert its rotational direction. The DIR signal could change over 5μS after ending of the last effective edge in forward direction and does not delay next pulse edge.

Last CP pulse in forward direction
Negative pulses method

≥5μ S   ≥0μ S

First CP pulse in next direction
Negative pulses method

Reverse signal DIR work this moment

If driver adopt double pulse CW / CCW mode, the first pulse of next direction (such as CCW) could be effective 5μs delay the last pulse(CW) effective edge of forward direction.

【2-phase motor Interface】

2-phase drive could be connected with 2-phase or 4-phase hybrid motor. Different motor winding have different connection methods, as follows:

For the two-phase four wire motor, the drive can be connected directly (see below Part I);

For the four-phase six-wire motor, the middle tap of the two lines are vacant, the other four wires are connected with drive (see Figure II);

For the four-phase five wire motor, the windings are not independent, the motor and drive can not be connected (see Figure III);

Eight four-phase eight wire motor, usually connected each two winding in parallel, and then connect with the drive (see below Part IV).

☞ Motor connect with drive directly ☑
☞ Motor can connect with drive directly, middle tap of the two lines are vacant ☑
☞ This motor could not connect with drive because windings are not independent ☒

☞ Motor can connect with drive in parallel ☑

【3-phase motor Interface】

Drive and 3-phase hybrid motor adopt three-wire connection. Drive output three phase sine wave current to the motor, the current is effective value nominal. Two types of motor winding connection: the triangle and star (see below):

Triangle Connection: Common used, high-speed and good performance, but requires a large drive current (1.73 times of the motor winding current).

Star connection: Drive output current is equal to motor winding current

U

$I=1.73i$

Drive output current I

V

Winding phase current

W

U

$I=i$

Drive input current I

V

Winding phase current

W
NOTE: Our company motors adopt triangle connection in the internal, only three lines leading out (excluding ground). Motor nominal current is not winding phase current, but the line current (i.e., drive output current). User set the drive output current to motor nominal current. If drive equip with motor of other manufacturers, user need to understand meaning of the nominal current. If the winding phase current is nominal value (e.g., 2.8A), the drive current be set phase current of 1.73 times (e.g., 4.8A).

【DIP switch settings】

M and T series drives have a 10-bit DIP switch for setting the step (segment), single / double pulse mode, self-test operation, automatic half current setting, the output current setting and so on. DIP switch 2 state is defined by 0 and 1, namely: ON = 0, OFF = 1. Detail setting please refers the corresponding description and the panel of the drive models. DIP switch must be settings before power.

【Driver output current setting】

M and T series drives have 16 speed output current optional, setting by the 4 bit DIP switches (sw7-10). Drive output sine wave current to motor. Considering the user habit, 2-phase motor nominal value is peak current; 3-phase motor nominal value is effective value current. Each bit of 4 bit DIP switches represents a certain current value (see table below) in enable condition (= 1) and"0" in non-enabled state (= 0). Adding four bit together represents drive output current.

General Settings is (For example, MZ-2H504A, 3.6A): starting from 7 bit, seventh represent 2.6A, as 3.6A> 2.6A, so seventh set to 1. Remain 3.6A-2.6A=1.0A is not set. Eighth represent 1.3A, as 1.0A<1.3A, so eighth non-enabled, set to 0. And so on, the last bit should be set to 1011, output current is 2.6+0+0.7+0.4=3.7A, in this case the error is 0.1A.

| Switch	Current in Enable condition（=1) (Example: Max Current is 5.0A)
7	2.6A
8	1.3A
9	0.7A
10	0.4A
