INTRODUCTION

A video wall is a set of screens accurately placed to create a single display. Screens may be one next to the other to compose a bigger, regular area or they may have irregular positions to create a non-conventional pattern.

In all of these cases a perfect synchronization of the content displayed is required to provide a sense of uniformity, no matter how the screens are placed.

The HMP100 let you control accurately when each item are displayed, enabling a very flexible solution for managing any type of video wall applications.

Application examples:

In public transportation, multiple displays are deployed along escalators. The content on the displays follows the user moving from one display to the next. This special effect increases the impact of the message to the user.

In retails shops, hotels and bars, multiple displays are deployed in the same hall to create an ambiance or a "leitmotif": animations can be created to move from one display to the next one creating global effects.

Two or three small size display can be grouped together to create a larger size display with higher impact to the audience.

MULTISCREEN DISPLAYS

HMP100s clocks are precisely time synchronized, letting the user control exactly when an item should be displayed. This feature can be used to schedule content to be displayed at a certain time of the day, or to synchronize the display of two or more HMP100. This enable the usage of the HMP100 in multiscreen displays.

The Hyper Media Director software (HMD) offers an intuitive way of managing multiscreen projects, trough the use of predefined templates and the possibility to create virtual devices for the publications process. In this case the same project will be used on all the HMP100 composing the multiscreen display, but each individual HMP100 will display only on part of the project. This let the user manage multiscreen display the same way as single screen displays.

To display content on multiple screen using HMD you need to perform the following operations.

- Create a project based on one of the multiscreen templates available in your install of HMD. This will be described in the design section of this document. For advanced user you can also create your own custom layout using the SpinetiX multiscreen syntax described in the advance part of this user guide.
- Create a virtual device to be able to publish your project on all the HMP100 composing your multiscreen display.
- Configure each HMP100 so that it knows its position in the multiscreen layout. It might also be necessary to configure the synchronization server for all the HMP100.
- Publish your project on the virtual device.

DESIGN

This chapter will show you how to create multiscreen content using the HMD software provided by SpinetiX.

Designing content for a multiscreen layout

To create a multiscreen layout you need to:

- Choose the layout of your screens
- Replace the index of your project by a multiscreen index
- Start working on your project

These three steps are described in more details in the following sections

Choosing your screens layout

HMD provides a set of predefined multiscreen layout. To select the correct layout for your screen configuration open the "Multiscreen" folder located under 'My templates'. A snapshot of the folder is shown in Figure 1. All predefined layout corresponds to adjacent screens creating a large scale videowall.

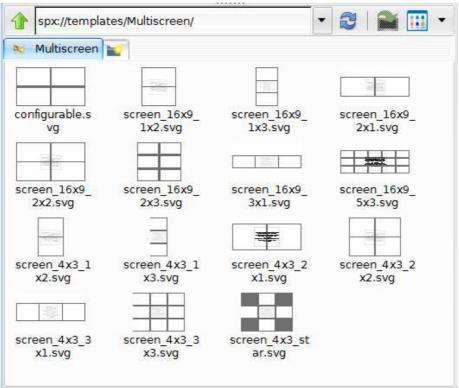

Figure 1 - Multiscreen templates

Different multiscreen layouts are provided. The icon shows you the configuration of the screens.

The template configurable.svg let you configure any kind of multiscreen matrix (NxM), including a possible border between the screens. To use this template, All screen composing the multiscreen layout must have the same dimension and the same aspect ratio. A snapshot of the configurable template is shown in Figure 2. The template let you configure the following items:

• Conventional multi-layer settings: duration, and new layer dimensions

- **Screen aspect ratio**: aspect ratio of the screens used to create your videowall. You can select horizontal layouts (16:9, 4:3, ...) or vertical layout (9:16, 3:4, ...) from the drop box or type any custom aspect ratio if needed.
- **Screen diagonal**: size of your individual screen. Can be expressed in inches (") or in centimeters (cm)
- Vertical and Horizontal frame border: Let you configure the size of the border of the screen in inches ("), centimeter (cm) or millimeters (mm). Note that you can use a negative value for the frame border for overlapping projected screens. In this case the HMP100 will add a blending gradient on the overlapping region.
- Array columns and rows: number of screen composing your videowall.

	Screen aspect ratio 9:16
	Screen diagonal 40"
	Vertical frame border 20mm
	Horizontal frame border 20mm
	Array columns 3
	Array rows 1

Figure 2: configurable.svg, a generic multiscreen template

It is possible to use custom layout for multiscreen design as explained in the advanced section of this documentation.

Creating a Multiscreen project

The second step for working with multiscreen content is to create your HMD project. This is done using the following steps:

- Create a new project in the usual way. You can select any aspect ratio as this setting will be override by the multiscreen templates
- Delete the index.svg from your project.
- Copy the desired layout to your project and rename it to index.svg.

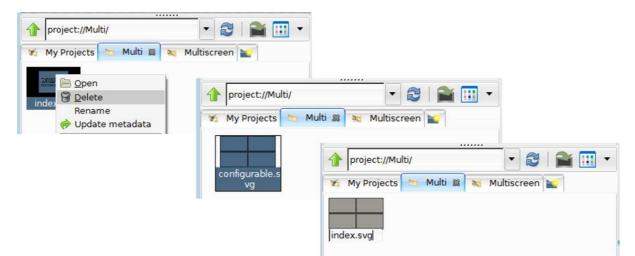

Figure 3: Using a multiscreen index file

Editing multiscreen content

Once the index file has been created you can start working on your project like for single display project. For instance you can:

- Add a background covering all the displayed content.
- Add playlist over the complete displayed area.
- Add a video covering one or multiple screen.
- ...

You can choose to see a global view of your project (Document) or a single screen portion at any time by pushing the "Multiscreen layout view" button, as shown in Figure 4.

Note that the content must obey the limitations of a single HMP100 unit. For instance the maximum resolution for a displayed video is SD. If you want to display video with higher resolution, the video must be cut into 4 or video of smaller sizes.

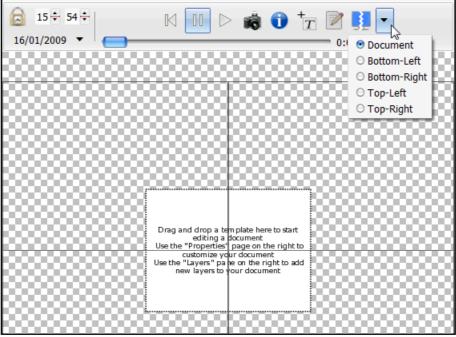

Figure 4 - Multiscreen layout view button

Configuring HMD and the HMP100

Before you can publish your project you need to configure your HMP100 to be ready to receive a multiscreen project. Two operations are needed: The creation of a virtual device in HMD and the configuration of the multiscreen ID of each HMP100.

Create a virtual device

It is possible to create group of devices under the My Device folder. Project can be published on single devices or on group of devices. This mechanism will be used to create a virtual device for multiscreen projects.

Creating a virtual device:

- Go to "My devices" in your "Workspace"
- Create a "New collection", rename it for example to "Videowall HMPs", as in Figure 5.
- Find the HMPs where you want to publish your project to, and move them into the newly created folder, see Figure 6.

Figure 6 - Move devices into group

Configure the Multiscreen ID

To configure the HMP100 multiscreen ID, you need to open the HTTP configuration server of each HMP100. You can use the 'Manage...' menu entry to do so:

- Open the "Videowall HMPs" folder (Figure 7), you will need to identify each HMP and assign its position in the layout
- Right click on the first HMP and choose "Manage...", the web interface will open.

Figure 7 - Identify each HMP

- Open the Network Settings configuration page
- Look for the "Multiscreen ID" under the "Identification" title, see Figure 8. This needs to be changed to exactly reflect the "Multiscreen Layout" screen names. e.g. "Top-Left", "Middle", "Bottom-Right". If you are using the configurable template then the screen are named "screen-1.1", "screen-1.2", ... depending on the screen position.
- This operation need to be performed for each HMP100.
- Once all the Multiscreen ID have been configured, you are now ready to publish your projects

nformation Status	Basic	Advanced

Publish your project on your device

To publish your multiscreen project to your group of devices, drag and drop your project folder on top of the "Videowall HMPs" folder icon (as shown in Figure 9); each HMP will be automatically updated and will display the assigned area of the video wall.

SYNCHRONIZATION

In order to be able to display content on multiple display, the clocks of the HMP100 must be synchronized. The synchronization is done using the Network Time Protocol (NTP).

How to synchronize HMPs?

The NTP protocol uses one or more NTP server to be able to control the precision of the internal clock. Using the NTP protocol it is possible to reach a precision as good as 1ms. This is more than sufficient to synchronize a video on multiple screens.

The HMP100 comes pre-configured with some public NTP servers, which are fine to regulate local date and time, but with the following limitations:

- Time precision around 200 ms
- Firewall needs to let NTP traffic through (UDP port 123),
- Synchronized content playback across several screens requires higher precision and reliability.

When using the HMP100 in a multiscreen display, the time precision between the HMP100 must be increased. This can be done using one of the following method:

- Configure a local or ISP provided NTP server
- Use a third party hardware plug & play servers
- Use a software based NTP server on a PC
- Use one HMP100 as NTP server for the other HMP100.

Configure NTP through the HTTP interface

Open your browser at your HMP100 configuration web page and choose the "Date/Time" tab on the left, the page shown in Figure 11 will appear:

Figure 11 - NTP Configuration

Once you are on the "Date/Time" configuration page, do the following:

- Make sure the NTP Server button is selected.
- Insert the address of your NTP server(s). Leave the "Monitor only" options unchecked. This option is needed only for advanced configurations.
- Leave the "Pause device and startup" to "0 s". If your HMP100 is using a local NTP server, you can increase this value to insure that your HMP100 will boot after your server in case of power cut in your installation for instance.
- Click on "Apply" to enable the new configuration

After you have configured all your HMPs with your local NTP server(s) they are ready to play synchronized content.

ADVANCED CONFIGURATION

Using an HMP as NTP server

Under certain circumstances you may want to use an HMP100 unit as time server for the other HMP100. For instance in case of:

- You don't have a local NTP server and want to use the public servers. In this case one HMP100 will synchronize to the public servers and the others HMP100 will be synchronize to this HMP100. This will provide a better accuracy between all the HMP100.
- The HMP100 do not have access to the Network. In this case one of the HMP100 is used as master whereas the other ones uses it's time as a reference. This will not prevent your installation from time drifting, but will insure that all the HMP100 are synchronized.
- You have two units that need to be synchronized. In this case the two unit can be connected by a cross-over cable and one HMP100 configured to be the time reference for the other.

In all scenario you will have two type of HMP100, a master and some slaves. One HMP100 will play the role of NTP server (master), the other will connect to it for getting the correct time (slaves). Before adopting this solution please note that this is less reliable than the standard one; in particular it's important to know that the clock of the HMP100s will drift apart from UTC time.

Configuration

Each HMP is ready to work as a NTP server, but a few parameters must be set to assure a smooth overall operation, thus execute the following procedure:

- Designate one and only one HMP unit as the master. It should have a static IP address. The clock should be already properly calibrated before use (for calibration refer to the "Troubleshooting" section at the end of this document)
- All other HMP100 units are slaves. They should also have static IP addresses but it is not strictly required

Configuration of the HMP100 acting as slaves:

- Identify the "slave" HMP100 and open its web interface
- In the Date/Time menu choose NTP Server and write the IP address of the "master" HMP100 in the first textbox (Server 1)
- Select "90 s" in the menu list corresponding to the option "Pause device at startup to wait for NTP servers by"
- Push the "Apply" button

Repeat this procedure for all your slave HMPs, but not the "master". The configuration settings are shown in Figure 12.

NTP Set	rver:	
		Monitor only
Server 1:	192.168.0.1

Apply		

Figure 12 - NTP slave configuration

Configuration of the HMP100 acting as master:

Identify the "master" HMP100 that will work as NTP server and configure it as follows through the web interface (also refer to Figure 13):

- In the Date/Time menu choose NTP Server and write the IP address of as many slave HMP100s with static IP addresses as possible in the server textboxes (Server 1, Server 2, etc.)
- Check the corresponding box(es) in the right column, under the title "Monitor only". The check box **must** be checked otherwise you will create a reference loop, and you system will not work correctly.
- Select "0 s" in the menu list corresponding to the option "Pause device at startup to wait for NTP servers by"
- Push the "Apply" button.

Figure 13 - NTP master configuration

With such a configuration, you will be able to switch on all your HMP100s at the same time and have them automatically synchronized between them.

Master/server architecture examples

As the number of HMP100s in your network grows up, several master/slave configurations become possible. The Figure 14 presents a set of possible configuration. The red arrows indicate the server address(es) entered in the master HMP100 configuration (Monitor only). The black arrows refer to the values entered for the slave HMP100(s). Refer to previous paragraph for configuration details.

Note that multiple levels of NTP hierarchies is strongly discouraged. For large installations it is more appropriate to invest in a NTP server.

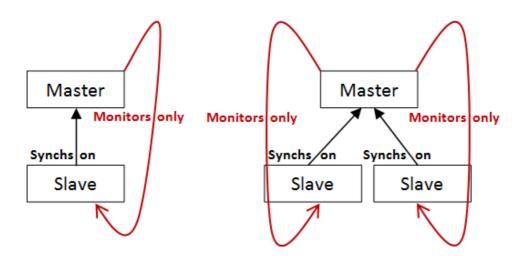

Figure 14 - NTP master/server architecture

Syntax for multiscreen synchronized content

The following XML code must be implemented into the index.svg file to create a multiscreen document:

Canvas and viewbox concepts

A **canvas** is the complete area physically described by the SVG index file, it may have (quite) any size, it generally corresponds to the rectangle formed by your videowall and it is usually larger than the size of one of your screens.

A **viewbox** is a subsection of the canvas, normally associated to a single screen. A viewbox can be placed anywhere inside the canvas area.

Example: in a 2x2 videowall, composed of 4 screens, the canvas will be 4 times larger than each of the 4 viewboxes associated to the 4 displays.

Multiscreen elements

The following elements provide information regarding the canvas size and the viewboxes size and position:

```
<svg

xmlns="http://www.w3.org/2000/svg"

xmlns:spx="http://www.spinetix.com/namespace/1.0/spx"
```

```
width="100%" height="100%"
viewBox="xc yc wc hc" >
    <spx:multiScreen>
        <spx:screen viewBox="x y w h" xml:id="screenID"/>
    </spx:multiScreen>
    [...]
</svg>
```

Value definitions:

viewBox="xc yc wc hc"

it's the space position and full size of the canvas, in pixels, where: xc is the x-axis coordinate of the top-left point of the canvas, yc is the y-axis coordinate of the top-left point of the canvas, wc is the total width of the canvas, hc is the total height of the canvas.

<spx:multiScreen> </spx:multiScreen> it's the element enabling the multiscreen functionality

<spx:screen viewBox="x y w h" xml:id="screenID"/>

it's the element representing each of the units that compose the complete canvas, its attributes are:

- ${\bf x}\,$ is the x-axis coordinate of the top-left point of this screen,
- ${\ensuremath{_{\rm Y}}}$ is the y-axis coordinate of the top-left point of this screen,
- w is the width of this screen,
- h is the height of this screen,

screenID is the screen identification name of your choice

Synchronization element

There are two possible techinique to ensure a corect synchronisation between content on different screens: The use of a schedule file or the usage of an inline begin time of a documemt. The predefined mulitscreen templates are using the inline begin time strategy. This means that synchronisation will be automatic when those templates are used.

The iCalendar (.ics) file

The first option for synchronizing content displayed on multiple screens is using an iCalendar file to contain the multiscreen file. Figure 15 shows the structure of the files to be created. The structure of your project should be as follow:

- Create an index.svg with you multiscreen setup. The file should contain the <spx:multiScreen> instructions.
- Create a iCalendar schedule file.
- Add your content designed for multiscreen into your schedule.

© 2009 SpinetiX S.A. All rights reserved.

ind	dex.svg (with multiscreen settings)
	schedule.ics
	content.svg

Figure 15 - iCalendar file for synchronization

This configuration let you use multiple schedules together with multiscreen content. You can use your custom SVG file or one of the multiscreen template as your index file.

If you want to use your multiscreen in a setup combining synchronised and unsynchronised content. The following alternative aproach is also possible (shown graphically in Figure 16:

- Create an index.svg file using the aspect ratio of a single screen
- Create a iCalendar schedule
- Create multiscreen files with the<spx:multiScreen> instructions and add them to the calendar
- Create single screen content and add them to the calendar. Note that you can use different calendar depending on the HMP100 (using the switch of JavaScript for instance). In this later case the content too be synchronized between multiple screen must start and end at the same time in the different calendards.

dex.svg vith the aspect ratio of a single screen)
schedule.ics
multiscreen.svg
singlescreen.svg

• Figure 16 - iCalendar file for synchronization, alternative option.

For further information on the scheduling functionality, please refer to the chapter "How to scheduling a Hyper Media project with HMD?" of this Userguide.

The spx:begin element

Instead of using a complete calendar file just for the synchronisation of the mulitple screens, it is possible to use an inline reduce schedule inside the index file. The schedule is described using a proprietarty tag in the svg element: spx:begin. The spx:begin.

describes the starting point of the document. Using this attribute has the same effect as putting the document in a schedule file starting at the same tiem as the one described by the attribute.

The spx:begin element can be used as follow:

```
<svg

xmlns="http://www.w3.org/2000/svg"

xmlns:spx="http://www.spinetix.com/namespace/1.0/spx"

height="100%" width="100%"

spx:begin="Thhmmss"

viewBox="xc yc wc hc" >

[...]

</svg>
```

Value definitions:

```
spx:begin="Thhmmss"
    it's the presentation beginning time, where:
    T is a fixed flag,
    hh is the hour of the day,
    mm are the minutes,
    ss are the seconds.
```

This feature is used by all the predefined multiscreen templates.

Additional syntax for multiscreen content

The following two methods are also available to build multiscreen contents:

- Extension of the SVG <switch> element
- JavaSript MULTI_SCREEN_ID variable

Extension of the SVG <switch> element

The SVG <switch> element allows to conditionally display SVG elements. This is a standard SVG element described in the <u>SVG specification</u>. For the handeling of multiscreen content a proprietary condition has been added by SpinetiX. This let you visualize a specific content based on the screenID of the player running the show. The <g> content is shown only if spx:multiScreenId is equal to "screenID". Multiple <g> contents, for different "screenID" values can be listed into the same <switch> element.

```
<switch>
<g spx:multiScreenId="screenID">
</g>
<switch>
```

Value definitions:

spx:multiScreenId="screenID"

spx:multiScreenId is the variable tested by the switch, it contains the ID of the
current screen

screenID is the value associated to each of the screens where the content will be displayed (e.g. "left", "right", "top", "bottom", etc).

Extension of JavaScript

When using JavaScript into a SVG file, the variable **MULTI_SCREEN_ID** is allways defined. It allows to visualize a specific content, based on the screenID of the player running the show.

Value definitions:

MULTI_SCREEN_ID="screenID"

MULTI_SCREEN_ID is the variable tested by the if statement, it contains theID of the current screen

screenID is the value associated to each of the screens where the content will be displayed (e.g. "left", "right", "top", "bottom", etc).

Examples

Screen layout with six screens

The following example creates a 2-columns, 3-rows grid with 6 16:9 screens set horizontally, as shown in Figure 16:

<svg <br="" xmlns="http://www.w3.org/2000/svg">xmlns:xlink="http://www.w3.org/1999/xlink"</svg>
<pre>xmlns:spx="http://www.spinetix.com/namespace/1.0/spx"</pre>
height="100%" width="100%"
<pre>spx:begin="T000000" viewBox="0 0 2560 2160" ></pre>
<spx:multiscreen></spx:multiscreen>
<spx:screen viewbox="0 0 1280 720" xml:id="TopLeft"></spx:screen>
<spx:screen viewbox="1280 0 1280 720" xml:id="TopRight"></spx:screen>
<spx:screen viewbox="0 720 1280 720" xml:id="MidLeft"></spx:screen>
<spx:screen viewbox="1280 720 1280 720" xml:id="MidRight"></spx:screen>
<spx:screen viewbox="0 1440 1280 720" xml:id="BotLeft"></spx:screen>
<pre><spx:screen viewbox="1280 1440 1280 720" xml:id="BotRight"></spx:screen></pre>

0,0 ↔ 1280 x 720 ¢	1280,0
0,720	1280,720
0,1440	1280,1440

↔ 2560 x 2160 ‡

Figure 16 - 2 x 3 grid layout

Screen layout with an empty border between the screens

To obtain a better whole effect you should take into account the space that may remain unusable between the displays, due to the screen frames. In this example we consider a thickness of 80 pixels for the screen frames (see Figure 17)

To create the final layout you must sum the internal borders thickness to the viewBox parameters, both in the (x,y) position and in the (w)idth, (h)eight sizes.

The following example creates the same grid as the previous one, but empty internal borders are also calculated:

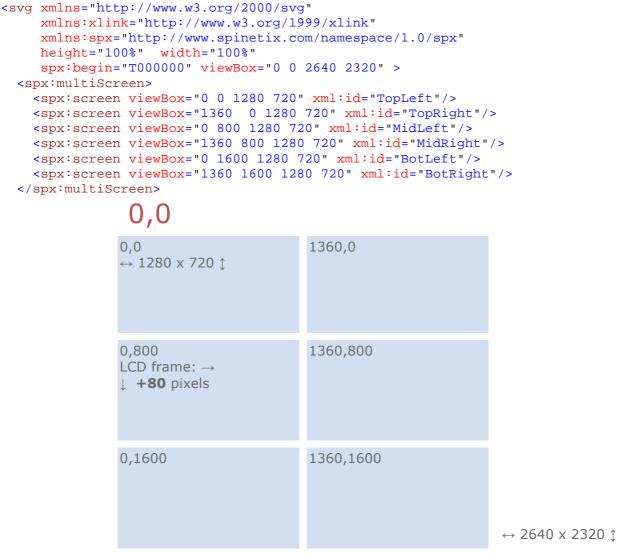

Figure 17 - 3 x 2 grid with frames border

Screen layout with "Spread displays"

A completely free pattern may be adopted for your screens; empty spaces between them are possible and custom positions can be assigned.

Screen contents can also overlap, increasing the sense of continuity between displays.

In this example we consider a wide area with some screens only covering a partial area of the whole space and with an overlapping corner.

The following code creates the area and pattern shown in Figure 18:

```
<svg xmlns="http://www.w3.org/2000/svg"
    xmlns:spx="http://www.spinetix.com/namespace/1.0/spx"
    xmlns:xlink="http://www.w3.org/1999/xlink"
    height="100%" width="100%"
    spx:begin="T000000" viewBox="0 0 4260 1920" >
    <spx:multiScreen>
        <spx:screen viewBox="50 50 1280 720" xml:id="TopLeft"/>
        <spx:screen viewBox="1706 240 1280 720" xml:id="TopRight"/>
        <spx:screen viewBox="852 1150 1280 720" xml:id="BotLeft"/>
        <spx:screen viewBox="2800 800 1280 720" xml:id="BotRight"/>
        <spx:screen>
```

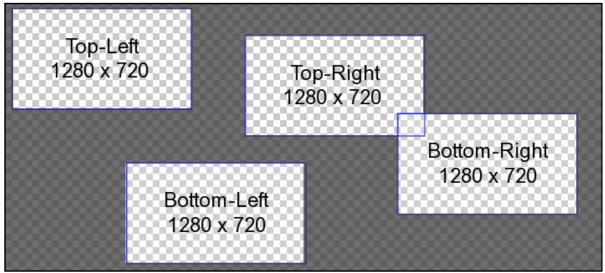

Figure 18 - Spread displays

Example: <switch> SVG element

The following example shows the use of the standard SVG $<{\tt switch}>$ element to display different contents on a screen based on its screenID (e.g. "left, "right", "top", "bottom" etc.).

```
<spx:multiScreen>
  <spx:screen viewBox="0 0 1280 720" xml:id="left"/>
  <spx:screen viewBox="0 0 1280 720" xml:id="right"/>
</spx:multiScreen>
<g display-align="center" font-family="Arial" font-size="100"</pre>
   text-align="center" transform="translate(320,180)">
  <switch>
    <q spx:multiScreenId="left">
      <textArea fill="#fed600" height="360" width="640" >I'm left screen!
      </textArea>
    </q>
    <g spx:multiScreenId="right">
      <textArea fill="#00d6fe" height="360" width="640" >I'm right screen!
      </textArea>
    </g>
    <g>
      <textArea fill="#d600fe" height="360" width="640" >No screen defined
      </textArea>
    </g>
  </switch>
</g>
```

Example: JavaScript

The following example shows the usage of the JavaScript MULTI_SCREEN_ID variable to control teh text content of a textArea item.

```
<spx:multiScreen>
 <spx:screen viewBox="0 0 1280 720" xml:id="left"/>
 <spx:screen viewBox="0 0 1280 720" xml:id="right"/>
</spx:multiScreen>
<script>
 <![CDATA[
 if (MULTI_SCREEN_ID == "left")
  document.getElementById("textId").textContent="I'm left!";
 else if (MULTI_SCREEN_ID == "right")
  document.getElementById("textId").textContent="I'm right!";
 else
  document.getElementById("textId").textContent="No screen defined!";
]]>
</script>
<g>
 <text x="50" y="50" xml:id="textID">_Text_will_be_here_</text>
</g>
```

TROUBLESHOOTING

Synchronized content over multiple screen need a correct configuration of teh HMP100 and a well designed hyper media project to work as expected. In case the project is not displayed correctly, here a first list of parameter to check before contacting <u>support@spinetix.com</u>.

NTP Synchronization

The content are not synchronized, i.e. one or more screens play their part of media earlier or later than the other displays.

Please check the following:

- Make sure that **NTP is enabled** through your web interface and that you have chosen a good NTP server (one or more):
 - It should be on your local network to be able to reach the few milliseconds of precision required.
 - Public NTP servers are usually too "far" to provide such a precision. Review section "Synchronization" for details on inserting NTP server addresses.
- Verify your HMP100s **NTP statistics**:
 - Values in the column "Time offset" should be as close to 0 as possible, as the example shown in Figure 19.
- Make sure that at least one NTP server is always reachable (at least one column "Reach" should be equal to 100%).

In case some of your NTP server can't be reached ("Status" column remains always "Initializing"), it may be behind a firewall or just wrongly configured. Check the NTP server configuration with your system administrator. For further details on the NTP protocol, please refer to http://www.ntp.org.

Display Settings Network Settings Media Sources Security Date/Time Serial Port Pull Mode Firmware Update Maintenance	Apply Change Time: Manual Time Settings: Date (DD MM YYYY): Time: 11 + 20 + 0 + Image: NTP Server: Monitor only

Figure 19 - NTP Statistics

If you used the **master/slave** configuration be careful to correctly implement the architectures explained in the "Configure an HMP as NTP server" paragraph, in section Synchronization, earlier in this chapter. Always create trees rather than loops between HMP100s. Double check your master ("Monitor only" selected) and slave configurations ("Monitor only" NOT selected).

Project creation

Verify that your index.svg file does contain the "spx:begin" attribute or that your project use a **schedule file** (.ics), as explained in section "Syntax for multiscreen synchronized content".

A good test to verify if you content uses a begin attribute or a calendar is to open the index.svg in HMD. If your project start from the beginning, then no schedule are present. If opening the project multiple times always shows the same starting point, then no schedule are present and the playback will not be synchronized.

Internal clock calibration.

The local clock on the device is not calibrated when shipped from factory. NTP behaves differently while the local clock is not yet calibrated and it will not synchronize as expected. Figure 20 below shows the configuration window before calibration is completed.

Server IP	Stratum	Status	Reach	Time offset	Delay	Dispersion	Poll interval
oopback	10	reject	100 %	0 ms	0 ms	0 ms	16 s
92.33.96.102	1	peer	100 %	-20 ms	14 ms	36 ms	64 s

Calibration is a necessary.

Figure 20 - Internal clock calibration

Calibration consists in finding the offset in frequency between the internal clock and a NTP reference and is necessary for normal operation of NTP.

The calibration process is started automatically and will take **approximately 60 minutes** when at least one NTP server (other than loopback) is available. Once the calibration data is saved it is reused when the device is rebooted or powered off.

To calibrate the clock of a device do the following:

- Start the device
- Look at the "NTP statistics" section of the "Date/Time" configuration page
- If at the end of the "NTP statistics" section it says that the clock is calibrated, no more operations are required, otherwise continue this procedure
- Check that at least one NTP server other than loopback is reachable and selected as peer
- $_{\odot}$ $\,$ Allow for some time for reachable servers to become peers
- If no NTP servers are reachable check that the NTP servers are correct and that the network configuration is working fine; if not, modify the settings and restart the procedure.
- Once a peer other than loopback is selected leave the device running for at least 70 minutes without rebooting
- After 70 minutes the local clock should be calibrated, reboot the device from the maintenance page (do not unplug the device before rebooting)
