

## The version control system git

Norbert Manthey

International Center for Computational Logic  
Technische Universität Dresden  
Germany

- ▶ Why do we need a version control system?
- ▶ How to use it - step by step
- ▶ What makes git different?

*"Logic is everywhere ..."*

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

Norbert

- ▶ sets up the document

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

- ▶ sets up the document
- ▶ sends it to me

Norbert

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

- ▶ sets up the document
- ▶ sends it to me
- ▶ waits for section 2

Norbert

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

- ▶ sets up the document
- ▶ sends it to me
- ▶ waits for section 2

Norbert

- ▶ write section 2, start section 4

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

**Peter**

- ▶ sets up the document
- ▶ sends it to me
- ▶ waits for section 2
  
- ▶ writes section 3, and sends

**Norbert**

- ▶ write section 2, start section 4

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

- ▶ sets up the document
- ▶ sends it to me
- ▶ waits for section 2
  
- ▶ writes section 3, and sends

Norbert

- ▶ write section 2, start section 4
  
- ▶ receive file, **merge**

## What is the problem?

- ▶ Assume: Peter and I write a paper
- ▶ Assume: Peter writes section 1,3 and 5, I write section 2 and 4

Peter

- ▶ sets up the document
- ▶ sends it to me
- ▶ waits for section 2
  
- ▶ writes section 3, and sends

Norbert

- ▶ write section 2, start section 4
  
- ▶ receive file, **merge**

- ▶ **This time:** just copy a whole section

## Is this it?

- ▶ Copying a whole passage is simple, however:
  - ▷ Who told you which part has been changed?
  - ▷ What should Peter do if Peter finds a typo in my text?
  - ▷ What should I do while I am waiting for Peter to finish his section?

## Is this it?

- ▶ Copying a whole passage is simple, however:
  - ▷ Who told you which part has been changed?
  - ▷ What should Peter do if Peter finds a typo in my text?
  - ▷ What should I do while I am waiting for Peter to finish his section?
- ▶ There exists **diff** tools ...

## Is this it?

- ▶ Copying a whole passage is simple, however:
  - ▷ Who told you which part has been changed?
  - ▷ What should Peter do if Peter finds a typo in my text?
  - ▷ What should I do while I am waiting for Peter to finish his section?
- ▶ There exists **diff** tools ...
  
- ▶ Can we work at the same document concurrently?
- ▶ Can I work offline?
- ▶ How does it work?

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

Peter

Norbert

- ▶ sets up the document, and **git**

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository

Norbert

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references

Norbert

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

### Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references
- ▶ commit changes locally

### Norbert

- ▶ clones repository, writes text

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

### Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references
- ▶ commit changes locally
- ▶ push changes to global repository

### Norbert

- ▶ clones repository, writes text
- ▶ commit changes locally

## How does it work?

- ▶ **Assume:** Peter and I write a paper with the version control system **git**
- ▶ **Assume:** Peter and I both have a local copy

### Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references
- ▶ commit changes locally
- ▶ push changes to global repository

### Norbert

- ▶ clones repository, writes text
- ▶ commit changes locally
- ▶ pull changes (global repository)

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

### Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references
- ▶ commit changes locally
- ▶ push changes to global repository
- ▶ continues writing

### Norbert

- ▶ clones repository, writes text
- ▶ commit changes locally
- ▶ pull changes (global repository)
- ▶ merges **automatically**

## How does it work?

- ▶ Assume: Peter and I write a paper with the version control system **git**
- ▶ Assume: Peter and I both have a local copy

### Peter

- ▶ sets up the document, and **git**
- ▶ sends the repository
- ▶ starts section 1, adds references
- ▶ commit changes locally
- ▶ push changes to global repository
- ▶ continues writing
- ▶ continues writing

### Norbert

- ▶ clones repository, writes text
- ▶ commit changes locally
- ▶ pull changes (global repository)
- ▶ merges **automatically**
- ▶ push changes (global repository)

## How does it work?

- ▶ **Requirements:**
  - ▷ A server where the global repository is stored
  - ▷ Access to this server for each participant
- ▶ **What are the basic steps?**
  - ▷ Set up the **git** repository
  - ▷ Create a local copy
  - ▷ Add files to the repository
  - ▷ Commit local changes
  - ▷ Pull changes from the global repository
  - ▷ Push changes to the global repository
  - ▷ In a conflict case: merge manually
- ▶ You can do much more, e.g. branch, roll back, ...

## How to set up a git repository?

- ▶ Choose a server and create a directory
- ▶ Create a repository there

```
ssh peter@spock
mkdir git
cd git
git init --bare --shared=group .
```

- ▶ **git init** creates the repository
- ▶ **-bare** creates the repository as not-useable
- ▶ **-shared=group** the repository can be shared with others from the same UNIX group
- ▶ **.** create the repository here

## How to create a local copy?

- ▶ Clone the global repository to your hard disk

```
mkdir paper
cd paper
git clone norbert@spock:~peter/git .
```

- ▶ **git clone** clones a repository to the specified place
- ▶ **spock: peter/git** is the link to the repository on the server
- ▶ **norbert** is my own user name on that server
- ▶ **.** create the repository here

## How to add files to the repository?

- ▶ Create files and adding them to the repository

```
echo "hello" >> paper.tex  
git add paper.tex
```

- ▶ **git add** adds files to the current **local** repository
- ▶ from now on, any following **git** command cares about this file

## How to add files to the repository?

- ▶ **Create files and adding them to the repository**

```
echo "hello" >> paper.tex  
git add paper.tex  
git commit -am "added first file"
```

- ▶ **git add** adds files to the current **local** repository
- ▶ from now on, any following **git** command cares about this file
- ▶ **git commit** records the changes locally
- ▶ **-am "added first file"** tells **git** to record all modifications and all added files
- ▶ in the same way, file modifications can be recorded by the repository

## How to pull changes from the global repository?

- ▶ Recording everything locally does not share the data
- ▶ The global repository might contain new data from others
- ▶ To get their data, changes need to be **pulled**

```
git pull origin master
```

- ▶ **git pull** download changes from the global repository
- ▶ **origin master** tells **git** where to get the changes from
- ▶ **origin** is the cloned repository
- ▶ **master** is the main branch

## How to pull changes from the global repository?

- ▶ Recording everything locally does not share the data
- ▶ The global repository might contain new data from others
- ▶ To get their data, changes need to be **pulled**

```
git pull origin master  
git commit -am "added first file"
```

- ▶ **git pull** download changes from the global repository
- ▶ **origin master** tells **git** where to get the changes from
- ▶ **origin** is the cloned repository
- ▶ **master** is the main branch
- ▶ pulling changes might result in **conflicts**
- ▶ conflict files need to be merged **manually**
- ▶ in each conflict file, conflicts are surrounded by “<<<” and “>>>”
- ▶ after manual merging, the conflict file needs to be **added** and **committed** again

## How to push changes to the global repository?

- ▶ Recording everything locally does not share the data
- ▶ To share your data, you need to **push** it into the global repository

```
git push origin master
```

- ▶ **git pull** download changes from the global repository
- ▶ **origin master** is the same as for **git pull**
- ▶ **Note:** good practice is to always **pull** before **pushing**

## Some limits

- ▶ **How does git work?**
  - ▷ **Basically, it is comparing altered lines**
- ▶ **What happens if both parties change the same line?**
  - ▷ **git will show a conflict**
- ▶ **What happens if both parties change the empty line below line X?**
  - ▷ **git will show a conflict**
- ▶ **One way to tackle this for  $\text{\LaTeX}$ ?**
  - ▷ **Brake lines frequently**
- ▶ **Still, the automatic merging is very powerful!**

## Working on your thesis

- ▶ You can also use the local repository only
  - ▷ Set up the repository (you want to use it and not share it)  
`git init .`
  - ▷ You can use this repository as backup/history
  - ▷ As usual, you can add files  
`git add`
  - ▷ You can commit changes  
`git commit -am "comment"`
- ▶ Of course, you could also use a global repository alone

## To sum up

- ▶ In the extreme case, first one user ...
  - ▷ sets up the repository `git init --bare --shared=group .`
  - ▷ clones the repository `git clone me@server:~me/pathToGit .`
  - ▷ adds all files `git add` and `git commit -am "comment"`
  - ▷ prepares the global repository `git push origin master`
  - ▷ and shares the link to the repository, e.g. `server:~me/pathToGit`
- ... and all users do
  - ▷ Clone the repository `git clone you@server:~me/pathToGit .`
  - ▷ Change files
  - ▷ Record changes locally `git commit -am "comment"`
  - ▷ Get the latest global changes `git pull origin master` (and sometime merge)
  - ▷ Share local changes `git push origin master`  
and repeat the last four steps until the document is final

## Conclusion

- ▶ Working on a shared document concurrently is easy
- ▶ Why should you use **git** and not **svn** or **cvs**?
  - ▷ You have a local repository
  - ▷ You can jump back to old versions locally (also in the plane)
- ▶ Is there a nice GUI?
  - ▷ Linux: **gitg** or **gitk**
  - ▷ Mac: **sourcetree** or **gitx**
- ▶ Still, its only four command line commands to know ...
  
- ▶ **Further information:** <http://schacon.github.com/git/user-manual.html>
