#### IMPORTANT SAFETY CONSIDERATIONS

**It is very important for the user to consider the possible adverse effects of power, wiring, component, sensor, or software failures in designing any type of control or monitoring system. This is especially important where economic property loss or human life is involved. It is important that the user employ satisfactory overall system design. It is agreed between the Buyer and Acromag, that this is the Buyer's responsibility.**

The information contained in this manual is subject to change without notice. Acromag, Inc. makes no warranty of any kind with regard to this material, including, but not limited to, the implied warranties of merchantability and fitness for a particular purpose. Further, Acromag, Inc. assumes no responsibility for any errors that may appear in this manual and makes no commitment to update, or keep current, the information contained in this manual. No part of this manual may be copied or reproduced in any form, without the prior written consent of Acromag, Inc.

## 2. GENERAL INFORMATION

---

The XMC-7 series modules are XMC modules with the heart of the design being a Xilinx 7 series reprogrammable FPGA. Re-configuration of the FPGA is possible via a direct download into the Flash configuration memory over the PCIe bus. The on board Flash memory loaded with configuration data allows automatic configuration of the FPGA on power-up.

These modules include the following interfaces: Four or eight high speed serial lanes are allocated to the XMC P15 connector. These lanes can be used for PCIe (PCI Express), Serial RapidIO, or 10 Gigabit Ethernet. The example design will support a four or eight lane Gen 1 PCIe implementation with one DMA channel for data transfer between the PCIe bus and on board DDR3 memory.

Eight (four on XMC-xxxF models) high speed serial lanes are also allocated to the XMC P16 connector. These serial lanes can be used for Serial RapidIO, PCIe, Gigabit Ethernet, XAUI, or Xilinx Aurora. The example design will support dual Aurora interfaces for use of these lanes. Two global clocks and 34 select I/O signals will also be provided on the P16 connector. Select I/O signals are 2.5V I/O pins that can be selected from single-ended I/O standards (LVCMOS, HSTL, and SSTL) and differential I/O standards (LVDS, HT, LVPECL, BLVDS, Differential HSTL and SSTL).

The P4 rear I/O connector will provide two global clock differential pairs, and 30 LVDS signal pairs.

The board features 128 Meg x 64-bit DDR3 SDRAM and 32 Meg x 16-bit parallel Flash. The parallel Flash provides storage for both the FPGA configuration data and MicroBlaze CPU program storage.

MODELS	FRONT I/O	P16 HS SERIAL	P16 SELECT I/O	P4 SELECT I/O
XMC-7A200	AXM modules	8 lanes	2 global clocks diff pairs, 17 LVDS signal pairs	2 global clocks diff pairs, 30 LVDS signal pairs
XMC-7A200CC	N/A	8 lanes	2 global clocks diff pairs, 17 LVDS signal pairs	2 global clocks diff pairs, 30 LVDS signal pairs
XMC-7KxxxAX	AXM modules	8 lanes	1 global clock diff pair, 15 LVDS signal pairs	2 global clocks diff pairs, 30 LVDS signal pairs
XMC-7KxxxCC	N/A	8 lanes	2 global clocks diff pairs, 17 LVDS signal pairs	2 global clocks diff pairs, 30 LVDS signal pairs
XMC-7KxxxF	2 SFP+, USB, JTAG, 2 global clock diff pairs, 11 LVDS signal pairs	4 lanes	2 global clocks diff pairs, 17 LVDS signal pairs	2 global clocks diff pairs, 30 LVDS signal pairs

## Ordering Information

The following table lists the orderable models and their corresponding operating temperature range. These maximum operating temperatures are determined using 75 % of the DSP slices and block RAMs at 200 MHz operating frequency. The amount of FGPA resources and clock frequency used by your application, if less than our test conditions, will possibly allow a higher operating temperature.

Models XMC-7A200CC, XMC-7K325CC and XMC-7K410CC are conduction-cooled models without front I/O.

**Table 1 The XMC-7 series boards are available in these configurations.**

MODELS	FPGA	OPERATING TEMPERATURE RANGE
XMC-7A200	Artix-7 XC7A200T	-40°C to +55°C (500 LFM airflow) <sup>1</sup>
XMC-7A200CC	Artix-7 XC7A200T	-40°C to +75° C cold-plate <sup>2</sup>
XMC-7K325AX	Kintex-7 XC7K325T	-40°C to +45°C (500 LFM airflow)
XMC-7K410AX	Kintex-7 XC7K410T	-40°C to +40°C (500 LFM airflow)
XMC-7K325CC	Kintex-7 XC7K325T	-40°C to +70°C cold-plate <sup>3</sup>
XMC-7K410CC	Kintex-7 XC7K410T	-40°C to +70°C cold-plate <sup>4</sup>
XMC-7K325F	Kintex-7 XC7K325T	-40°C to +55°C (500 LFM airflow)
XMC-7K410F	Kintex-7 XC7K410T	-40°C to +55°C (500 LFM airflow)

<sup>1</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

<sup>2</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R) between the carrier cold plate and the XMC module heatsink.

<sup>3</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R ) between the carrier cold plate and the XMC module heatsink.

<sup>4</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R ) between the carrier cold plate and the XMC module heatsink.

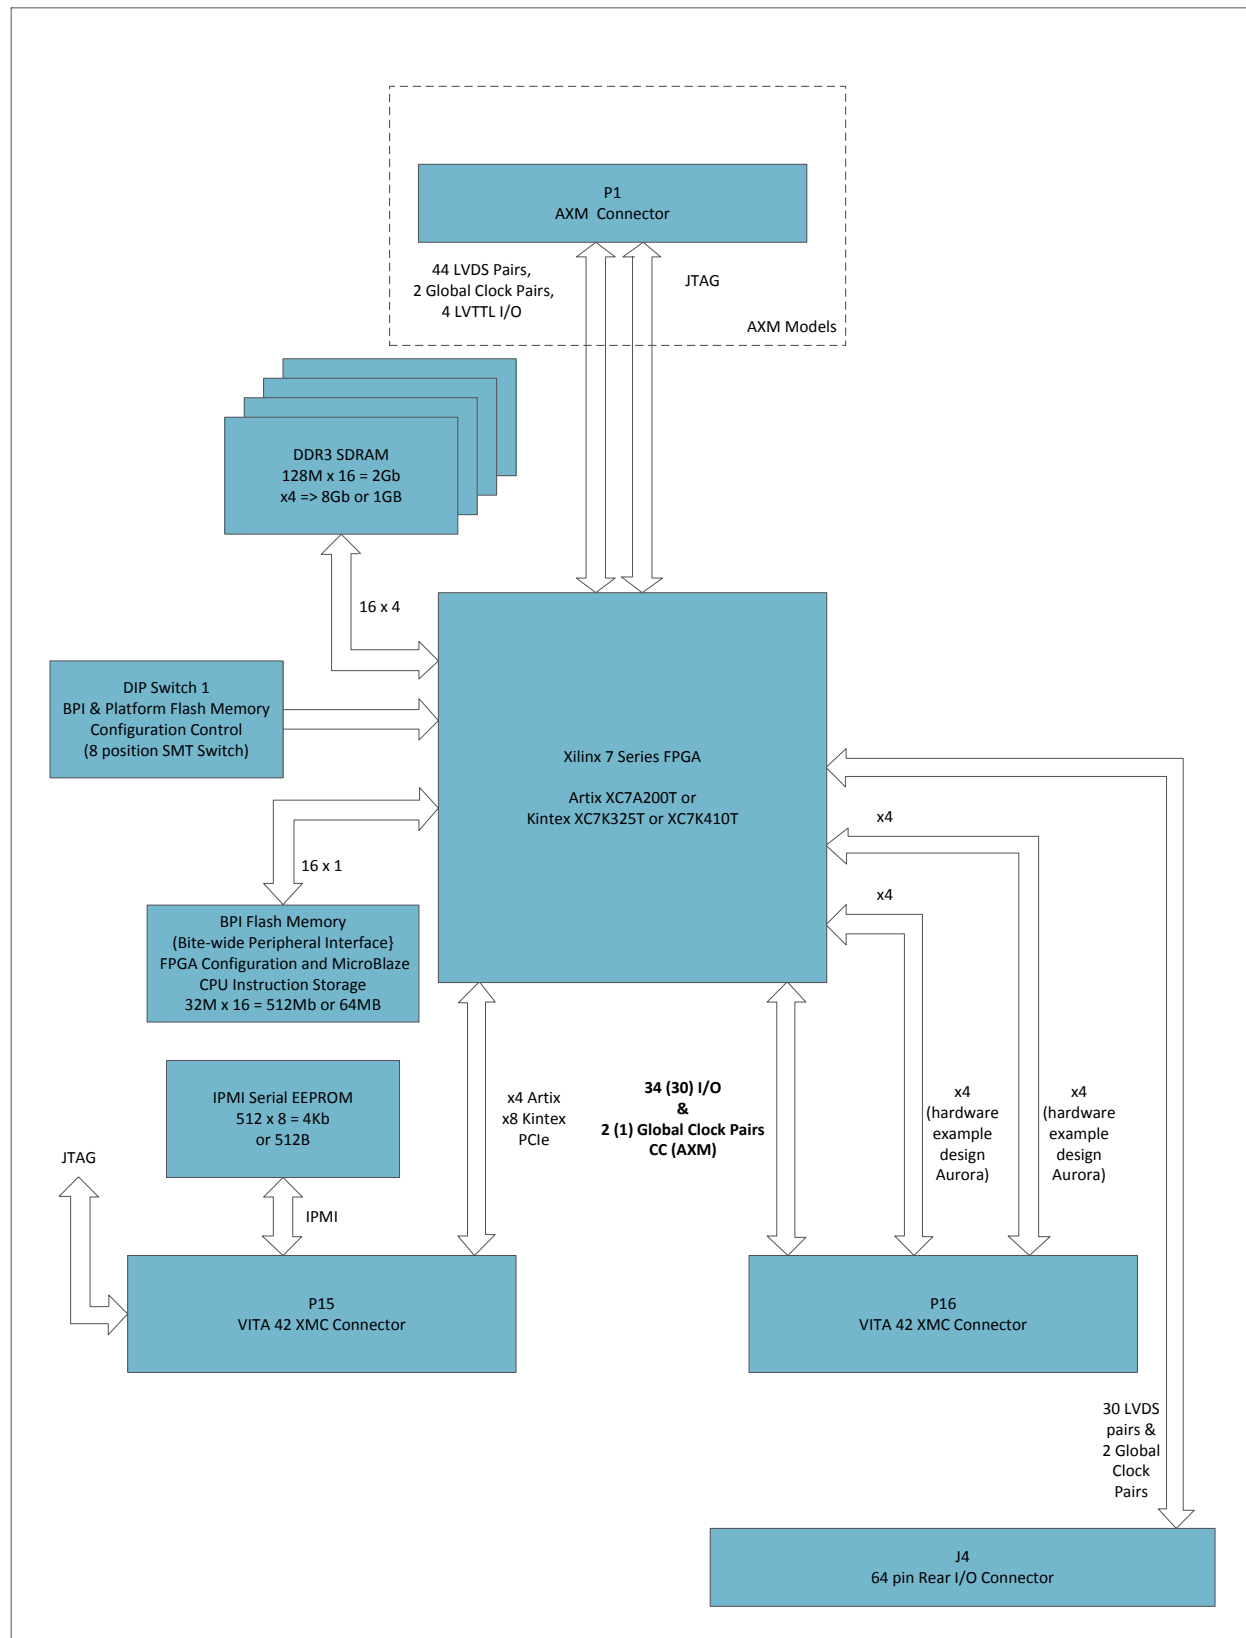

Figure 1 Block Diagram AXM / CC Models

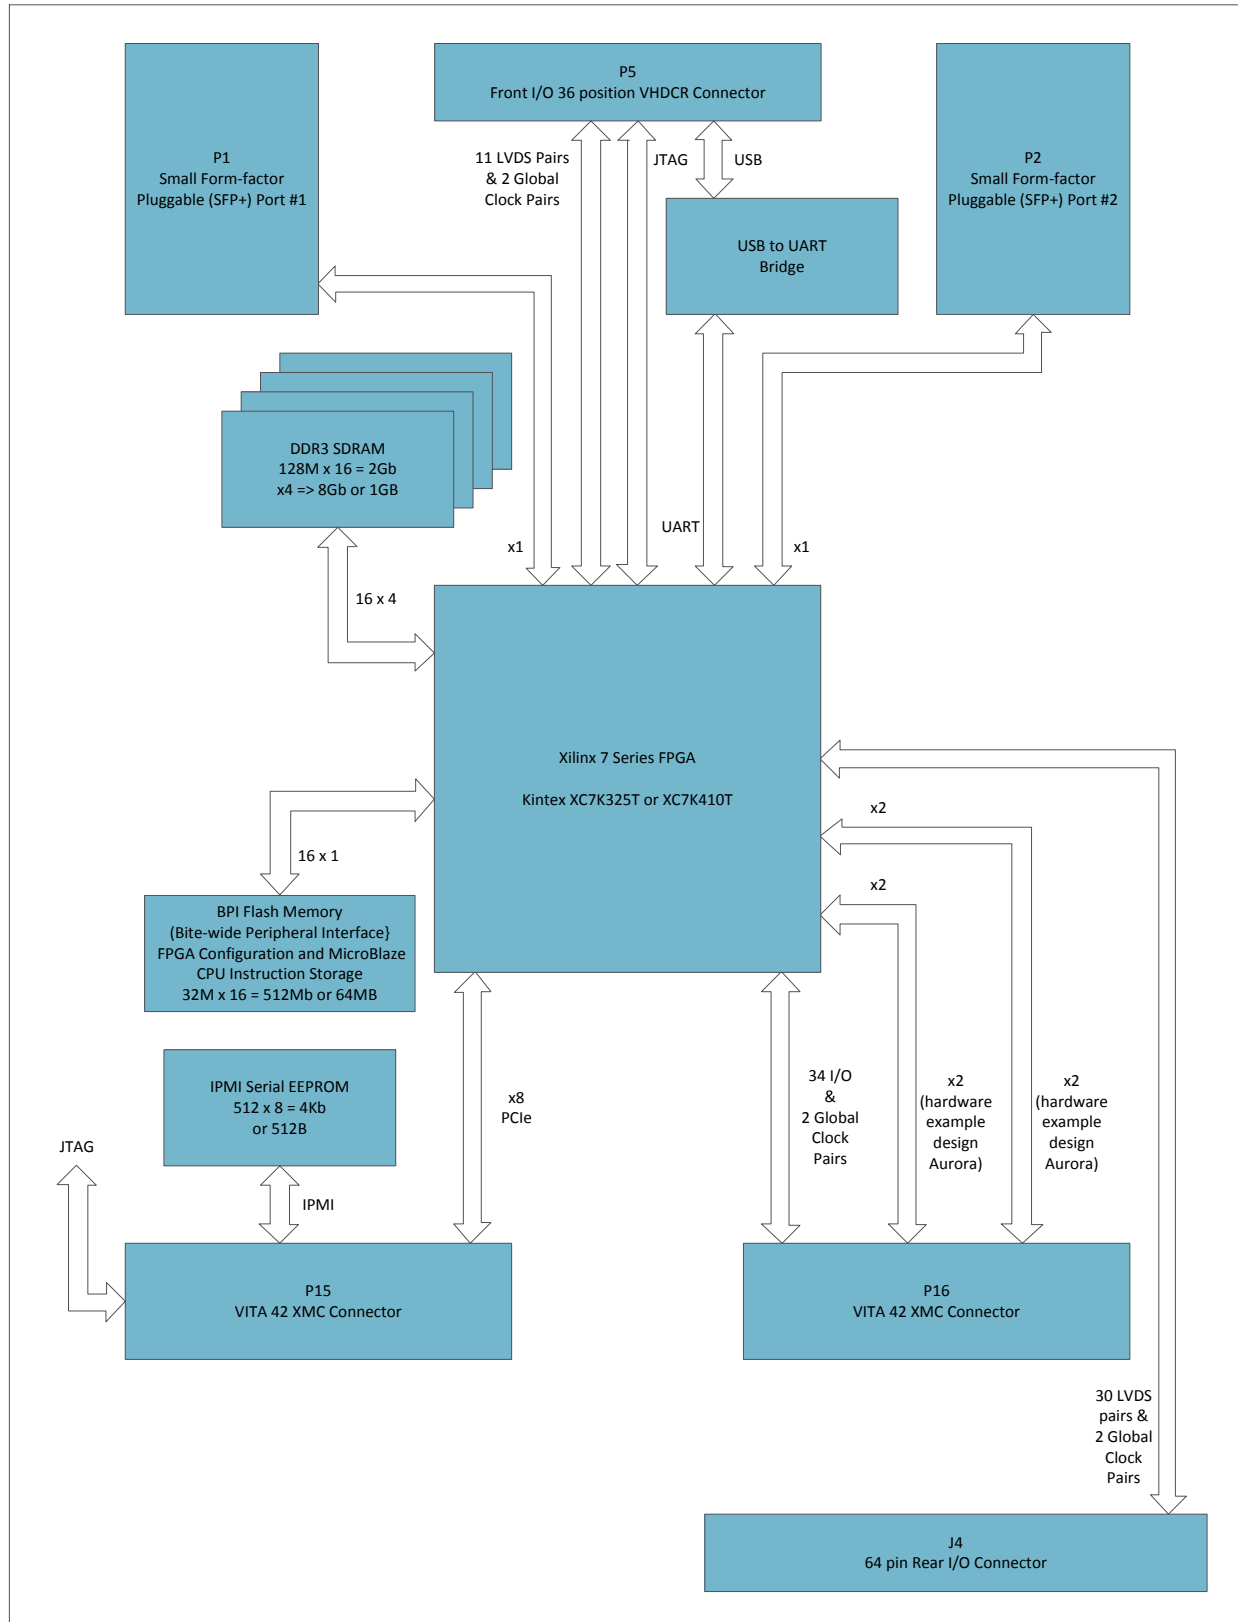

Figure 2 Block Diagram F Models

## KEY FEATURES

The block diagram shown in Figure 1 illustrates the key features listed below. Features common to all models are listed first, followed by model specific features.

### Common Features:

- **Reconfigurable Xilinx FPGA** –The FPGA loads its configuration data from flash memory each time power is applied to the module. The host processor can be used to change the flash configuration memory via the PCIe bus. This provides a means for creating custom user defined designs. The FPGA will configure from the updated flash memory on the next power cycle.
- **DDR3 SDRAM** –128 Meg x 64-bit DDR3 SDRAM is connected to the FPGA.
- **Interface to Rear P4 Connector** – The FPGA is directly connected to 64 pins of the rear P4 connector. All 2.5 Volt I/O standards supported by the Xilinx 7 series devices are available. The example design implements LVCMOS single ended signaling.
- **P15 High Speed Interface** –Eight high speed serial lanes are allocated to the XMC P15 connector. These lanes can be used for an 8 lane PCIe (PCI Express) implementation, Serial RapidIO, or 10 Gigabit Ethernet. The Kintex example design includes an 8 lane Gen 1 PCIe implementation while the Artix example design includes a 4 lane Gen 1 PCIe implementation.

### Features supported on AX models:

- **Acromag AXM Module Support** – various mezzanine modules (“AXM” model prefix), ordered separately, allow the user to select the Front I/O required for their application.
- **P16 High Speed Interface** – Eight high speed serial lanes are allocated to the XMC P16 connector in the AX models. These lanes can be used for Serial RapidIO, PCIe, 10 Gigabit Ethernet, or Xilinx Aurora. The example design supports a pair of four lane Aurora interfaces in a chip to chip loopback implementation.

### Features supported on CC models:

- **P16 High Speed Interface** – Eight high speed serial lanes are allocated to the XMC P16 connector in the CC model. These lanes can be used for Serial RapidIO, PCIe, 10 Gigabit Ethernet, or Xilinx Aurora. The example design supports a pair of four lane Aurora interfaces in a chip to chip loopback implementation.

### Features supported on F models:

- **P16 High Speed Interface** – Four high speed serial lanes are allocated to the XMC P16 connector on the F model. These lanes can be used for Serial RapidIO, PCIe, or Xilinx Aurora. The example design supports a pair of two lane Aurora interfaces in a chip to chip loopback implementation.

- **Interface to Front I/O Connector** – The FPGA is directly connected to a front I/O connector. All 2.5 Volt I/O standards supported by the Xilinx 7 series devices are available on 13 signal pairs. A JTAG port is included for configuration and for use with the Xilinx ChipScope FPGA debugger. The USB UART interface provides a COMM port device for the host processor to connect to the MicroBlaze UART.
- **Example Design Provided** – The example design includes implementation of the DDR3 memory, PCIe bus 8 lane Gen 1, control of digital front and rear I/O, and 1 Gig Ethernet 1000-X interface to the SFP+ modules.

## PCIe Interface Features

- **PCIe Bus** – The example design includes a PCI Express Generation 1 interface operating at a bus speed of 2.5 Gbps per lane per direction. On Kintex based models eight lanes are supported. Artix models support 4 lanes. Maximum payload size is 1024 bytes. Up to 4 GBytes/sec burst data transfer rate can be achieved when utilizing eight lanes.
- **PCIe Bus Master** – The PCIe interface logic becomes the bus master to perform DMA transfers.
- **DMA Operation** – The example design includes a DMA controller to move data between the DDR3 memory and the PCIe bus interface.
- **Compatibility** – PCI Express Base Specification v2.1 compliant PCI Express Endpoint. Provides one multifunction interrupt. The XMC-7 series modules are compatible with XMC VITA 42.3 specification for P15.

## Software

The XMC-7 series products require support drivers specific to your operating system. Supported operating systems include: Linux, Windows, and VxWorks.

## ENGINEERING DESIGN KIT

Acromag provides an engineering design kit for the XMC products (sold separately), a “must buy” for first time 7 series module purchasers. The design kit (model XMC-7KA-EDK) provides the user with the basic information required to develop a custom FPGA program for download to the Xilinx FPGA. The design kit includes a CD containing: schematics, parts list, part location drawing, example VHDL source, and other utility files. The 7 series modules are intended for users fluent in the use of Xilinx FPGA design tools.

## Windows®

Acromag provides software products (sold separately) to facilitate the development of Windows® applications interfacing with Acromag PMC, XMC, and VPX I/O board products, PCI and PCIe I/O Cards, and CompactPCI I/O Cards. This software (model PCISW-API-WI) consists of low-level drivers and Dynamic Link Libraries (DLLs) that are compatible with a number of

programming environments. The DLL functions provide a high-level interface to boards eliminating the need to perform low-level reads/writes of registers, and the writing of interrupt handlers.

### VxWorks®

Acromag provides a software product (sold separately) consisting of VxWorks® software. This software (Model PMCSW-API-VXW) is composed of VxWorks® (real time operating system) libraries for all Acromag PMC, XMC, and VPX I/O board products, PCI and PCIe I/O Cards, and CompactPCI I/O Cards. The software is implemented as a library of “C” functions which link with existing user code to make possible simple control of all Acromag PCI and PCIe boards.

### Linux®

Acromag provides a software product consisting of Linux® software. This software (Model PMCSW-API-LNX) is composed of Linux® libraries for all Acromag PMC, XMC, and VPX I/O board products, PCI and PCIe I/O cards, and CompactPCI I/O cards. The software supports X86 PCI bus only and is implemented as library of “C” functions which link with existing user code to make possible simple control of all Acromag PCI and PCIe boards.

## Signal Interface Products (XMC-7K325F and XMC-7K410F Models)

Accessory cables that interface to the front VHDCI connector and SFP+ ports are available from Acromag.

### VHDCI Cable

Acromag provides a cable that brings the 36 pins of the VHDCI front I/O connector out to a 50 pin SCSI connector. The Acromag part number is 5025-921. See Table 5 Front VHDCI Field I/O Pin Connections. A [cable drawing](#) is also provided in the accessories section at the end of this manual.

### Direct Attach Cable

Acromag provides a 1 meter direct attach cable that connects one SFP+ port to another SFP+ port. This passive cable can be used to carry 10 Gb Ethernet or Aurora signals to another nearby XMC-7Kxxx module. The Acromag part number is TAPCABLE1M. A [cable drawing](#) is provided in the accessories section at the end of this manual.

### 1000BASE-T Copper SFP Transceiver

Acromag provides a Copper SFP Transceiver that is compatible with the Gigabit Ethernet and 1000BASE-T standards as specified in IEEE Std 802.3. It has an RJ-45 connector and is RoHS compliant and lead-free. The Acromag part number is 5028-455. A [cable drawing](#) is provided in the accessories section at the end of this manual.

### 2.125 Gb/S Short-Wavelength SFP Transceiver

Acromag provides 2.125 Gb/s Short Wavelength SFP Transceiver that is compatible with the Gigabit Ethernet standard as specified in IEEE Std 802.3 and Fibre Channel FC-PI-2 Rev. 5.0. It is RoHS compliant and lead-free. It supports up to 2.125 Gb/s bi-directional data links. The module uses an 850nm Oxide VCSEL laser transmitter. The Acromag part number is 5028-452. A [drawing](#) is provided in the accessories section at the end of this manual.

### 3. PREPARATION FOR USE

#### UNPACKING AND INSPECTION

Upon receipt of this product, inspect the shipping carton for evidence of mishandling during transit. If the shipping carton is badly damaged or water stained, request that the carrier's agent be present when the carton is opened. If the carrier's agent is absent when the carton is opened and the contents of the carton are damaged, keep the carton and packing material for the agent's inspection.

For repairs to a product damaged in shipment, refer to the Acromag Service Policy to obtain return instructions. It is suggested that salvageable shipping cartons and packing material be saved for future use in the event the product must be shipped.

This board is physically protected with packing material and electrically protected with an anti-static bag during shipment. It is recommended that the board be visually inspected for evidence of mishandling prior to applying power.

The board utilizes static sensitive components and should only be handled at a static-safe workstation.

#### CARD CAGE CONSIDERATIONS

Refer to the specifications for loading and power requirements. Be sure that the system power supplies are able to accommodate the power requirements of the carrier board, plus the installed XMC module, within the voltage tolerances specified.

Adequate air circulation must be provided to prevent a temperature rise above the maximum operating temperature and to prolong the life of the electronics. If the installation is in an industrial environment and the board is exposed to environmental air, careful consideration should be given to air-filtering.

#### Board Installation

Remove power from the system before installing board, cables, termination panels, and field wiring.

## P15 Primary XMC Connector

The P15 XMC connector is wired per the VITA 42.0 standard. Most of the P15 signals connect directly to the user programmable FPGA. The P15 connector provides the 8 lane PCI Express interface to the host processor, a JTAG interface, and an I<sup>2</sup>C interface to a serial memory device. XMC-7A200, XMC-7K325AX, and XMC-7K410AX models require 12V and -12V power when an AXM module is installed that requires +12V and -12V power. All models require 3.3AUX power in order to maintain the encryption key stored in volatile memory, if that feature is required. The JTAG signals connect to the FGPA for configuration and debugging.

**Table 2 P15 Primary XMC Connector**

## P16 Secondary XMC Connector

The P16 secondary XMC connector connects directly to the user-programmable FPGA for both high speed Giga bit data signals and standard I/O user signals. The user I/O pins are connected to FPGA banks with VCCO pins powered by 2.5 volts. Thus these user I/O pins support the 2.5 volt I/O standards. The IOSTANDARD attribute can be set in the design constraints file (.xdc). For example, P16 user I/O can be defined for LVDS\_25 (Low-Voltage Differential Signaling). The example design configures the P16 I/O as LVCMOS25 (low voltage CMOS) in the design constraints file. The tables included in the P16 Input Data Register and P16 Output Data Register sections

can be used to map the LVCMOS signal to the signal names given in this table. The 2.5 volt I/O standards available are listed in the [7 Series FPGAs SelectIO Resources User Guide](#) available from Xilinx.

**Table 3 P16 Secondary XMC Connections**

Pin	A	B	C	D	E	F
1	DP00+	DP00-	S18G_N	DP01+	DP01-	S18G_P
2	GND	GND	S16_N	GND	GND	S17_N
3	DP02+	DP02-	S16_P	DP03+	DP03-	S17_P
4	GND	GND	S14_N	GND	GND	S15_N
5	DP04+	DP04-	S14_P	DP05+	DP05-	S15_P
6	GND	GND	S12_N	GND	GND	S13_N
7	DP06+	DP06-	S12_P	DP07+	DP07-	S13_P
8	GND	GND	S10_N	GND	GND	S11_N
9	N.C. <sup>5</sup>	N.C.	S10_P	N.C.	N.C.	S11_P
10	GND	GND	S8_N	GND	GND	S9_N
11	DP10+	DP10-	S8_P	DP11+	DP11-	S9_P
12	GND	GND	S6_N	GND	GND	S7_N
13	DP12+	DP12-	S6_P	DP13+	DP13-	S7_P
14	GND	GND	S4_N	GND	GND	S5_N
15	DP14+	DP14-	S4_P	DP15+	DP15-	S5_P
16	GND	GND	S2_N	GND	GND	S3_N
17	DP16+	DP16-	S2_P	DP17+	DP17-	S3_P
18	GND	GND	S0G_N	GND	GND	S1_N
19	REFCLK0_P	REFCLK0_N	S0G_P	N.C.	ROOT0_N	S1_P

The example design implements 2.5 volt LVCMOS I/O at the P16 connector.

Alternatively, 2.5 volt LVDS I/O can be used on the P16 connector.

Configured as LVDS signal pairs, the signals can be grouped to match the ANSI/VITA 46.0 X38s pattern map. A total of 19 differential signal pairs are provided (16 on AX models). These differential signal pairs connect to column C and F of the P16 XMC connector as shown in Table 3. For example S3\_P and S3\_N form a signal pair. There are two global clock differential pairs available (S0G\_P, S0G\_N) and (S18G\_P, S18G\_N). The P identifies the Positive input, the N identifies the Negative input.

The XMC P16 Secondary connector is a 114-pin Samtec ASP-103614-05 connector. The connector complies with ANSI/VITA 42.3-2006.

## Rear P4 Field I/O Connector

The rear I/O P4 connector connects directly to the user-programmable FPGA. The VCCO pins are powered by 2.5 volts and thus will support the 2.5 volt I/O standards. The IOSTANDARD attribute can be set in the design constraints file

<sup>5</sup> N.C. – not connected

(XDC). The example design configures the rear P4 I/O as LVCMOS25 (low voltage CMOS) in the design constraints file. The tables included in the P4 Rear Input Data Register and P4 Rear Output Data Register sections can be used to map the LVCMOS signal to the signal names given in the table below.

The rear I/O can alternatively be configured for LVDS\_25 (Low-Voltage Differential Signaling) in the design constraints file. The 2.5 volt I/O standards available are listed in the [7 Series FPGAs SelectIO Resources User Guide](#) available from Xilinx.

Two of the signal pairs (RIO0\_GCLK\_P/N and RIO31\_CCLK\_P/N) are connected to clock capable I/O pins on the FPGA. These pins provide a direct path to global clock buffers in the FPGA.

As LVDS signal pairs, the signals can be grouped as 32 LVDS I/O pairs. The LVDS pairs are arranged in the same row in Table 4. For example, RIO1\_P and RIO1\_N form a signal pair. The P identifies the Positive input while the N identifies the Negative input.

**Table 4 Rear Field I/O Pin Connections**

Ch.	Positive Pin Description	Pin	Negative Pin Description	Pin
0	RIO0_GCLK_P	1	RIO0_GCLK_N	3
1	RIO1_P	2	RIO1_N	4

21	RIO21_P	42	RIO21_N	44
22	RIO22_P	45	RIO22_N	47
23	RIO23_P	46	RIO23_N	48
24	RIO24_P	49	RIO24_N	51
25	RIO25_P	50	RIO25_N	52
26	RIO26_P	53	RIO26_N	55

Ch.	Positive Pin Description	Pin	Negative Pin Description	Pin
27	RIO27_P	54	RIO27_N	56
28	RIO28_P	57	RIO28_N	59
29	RIO29_P	58	RIO29_N	60
30	RIO30_P	61	RIO30_N	63
31	RIO31_GCLK_P	62	RIO31_GCLK_N	64

The example design implements 2.5volt LVCMOS I/O to the rear connector.

Alternatively, 2.5volt LVDS I/O can be used on the rear connector.

This connector is a 64-pin female receptacle header (AMP 120527-1 or equivalent) which mates to the male connector on the carrier board (AMP 120521-1 or equivalent).

#### Front Panel Field I/O Connector (XMC-7K325F and XMC-7K410F models)

The front panel provides access to a 36 pin VHDCI connector and two SFP+ port connectors. The VHDCI connector provides interfaces to JTAG, USB and 26 single ended or 13 differential I/O signal pairs. Two of the signal pairs are routed to global clock pins on the Kintex 7 device.

The 26 front I/O signals connect directly to the user-programmable FPGA. The VCCO pins are powered by 2.5 volts and thus will support the 2.5 volt I/O standards. The IOSTANDARD attribute can be set in the user constraints file (UCF). The example design configures the Front I/O as LVCMOS25 (low voltage CMOS) in the user constraints file. The tables included in the Front Input Data Register and Front Output Data Register sections can be used to map the LVCMOS signals to the signal names given in the table below.

The Front I/O can alternatively be defined for LVDS\_25 (Low-Voltage Differential Signaling) in the user constraints file. The 2.5 volt I/O standards available are listed in the Kintex-7 User Guide available from Xilinx.

**Table 5 Front VHDCI Field I/O Pin Connections**

Ch.	Positive Pin	Pin	Negative Pin	Pin
	TCK	1	TMS	19
	TDO	2	TDI	20
	GND	3	+2.5V	21

	USB_D+	17	USB_D-	35
	USB_VBUS(from host)	18	GND	36

The example design implements 2.5volt LVCMOS I/O at the front connector.

Alternatively, 2.5volt LVDS I/O can be used on the front connector.

This connector is a 36-pin female receptacle header (SAMTEC VHDCR-36-01-M-RA or equivalent) which mates to the male connector.

#### SFP+ Module Connectors (XMC-7K325 and XMC-7K410F models)

**Table 6 SFP+ Module Pin Connections**

Pin	Symbol	Pin Description
1	VeeT	Module Transmitter Ground
2	Tx_Fault	Module Transmitter Fault
3	Tx_Disable	Transmitter Disable
4	SDA	2-wire Serial Interface Data Line
5	SCL	2-wire Serial Interface Clock
6	Mod_ABS	Module Absent
7	RS0	Rate Select
8	Rx_LOS	Receive Loss of Signal Indication
9	VeeR	Module Receiver Ground
10	VeeR	Module Receiver Ground
11	VeeR	Module Receiver Ground
12	RD-	Receiver Inverted Data Output
13	RD+	Receiver Non-Inverted Data Output
14	VeeR	Module Receiver Ground
15	VccR	Module Receiver 3.3 V Supply
16	VccT	Module Transmitter 3.3 V Supply
17	VeeT	Module Transmitter Ground
18	TD+	Transmitter Non-Inverted Data Input
19	TD-	Transmitter Inverted Data Input
20	VeeT	Module Transmitter Ground

#### Ethernet MAC IDs (XMC-7K325F and XMC-7K410F models)

Two Ethernet MAC ID (address) numbers have been reserved for each XMC-7K325F and XMC-7K410F units. The numbers are printed on the labels attached to the board. The example design provided by Acromag includes MicroBlaze software running the LWIP TCP/IP network protocol suite. The

MAC ID for each port is set by the software. If your application uses the example design as a base for your project, replace the MAC IDs in the “C” source with the IDs printed on the label.

### Non-Isolation Considerations

The board is non-isolated, since there is electrical continuity between the logic and field I/O grounds. As such, the field I/O connections are not isolated from the system. Care should be taken in designing installations without isolation to avoid noise pickup and ground loops caused by multiple ground connections.

## 4. PROGRAMMING INFORMATION

---

This Section provides the specific information necessary to program and operate the board.

### GETTING STARTED

1. The XMC-7 series modules are shipped with the example design FPGA bitstream stored in the flash memory. This example design bitstream operates with the driver software included in the support package. Upon power-up the XMC-7 series module will automatically configure the FPGA with the example design bitstream stored in flash. As a first step become familiar with the appropriate example design for your model. The board will perform all the functions of the example design as described in this manual.

The Example Design Memory Map section gives a description of the I/O registers provided by the example design. It will allow testing of PCIe interface, read/write of DDR3 memory, all digital I/O ports, interrupts, P16 Aurora loopback, and DMA operation. It is strongly recommended that you become familiar with the board features by using the example design as provided by Acromag.

**CAUTION:** Do not attempt to reconfigure the flash memory until after you have tested and become familiar with the XMC-7 series module as provided in the example design.

2. After you are familiar with the module's features and have tested it using the example design, proceed to the DESIGN MODIFICATION WALK THROUGH. Here you will modify the example design VHDL code slightly. The configuration flash must be overwritten to test your design. Once the flash is erased you will not be able to go back to the example design by simply powering down and restarting the board. If your code does not function as desired you may need to reload the Acromag design example. You can reload the Acromag example design via the JTAG port using the Xilinx Vivado tool. Upon power-up, the example design provided by Acromag will again be loaded into the FPGA. Note: XMC-7A200AX/CC models are delivered with two copies of the example design bitstream stored in flash memory. One of the copies is stored in a write protected section of the flash. If the configuration

file loaded from the writeable section of flash fails to support the flash write function via the PCIe bus, a recovery method is available. The FPGA can be directed to configure from the backup bitstream by opening switch SW1 position 3 shown in Figure 3.

See the Flash Configuration section for a description of the steps required to write new data or to reprogram the example design code to the flash device.

**Figure 3 XMC-7A200 Switch Location**

## FPGA Configuration

The XMC-7 series modules support configuration in the following modes:

- Master BPI-Up using Linear BPI Flash device.
- JTAG using Xilinx external program cable.

The FPGA configuration bitstream is loaded from flash memory on power-up.

## PCIe CONFIGURATION ADDRESS SPACE

This XMC-7 series modules are PCI Express Base Specification Revision v2.1 compliant.

The PCIe bus is defined to address three distinct address spaces: I/O, memory, and configuration space. This board can be accessed via the PCIe bus memory, and configuration spaces.

The card's configuration registers are initialized by system software at power-up to configure the card. The board is a Plug-and-Play PCIe card. As a Plug-and-Play card the board's base address and system interrupt request are not selected via jumpers but are assigned by system software upon power-up via the configuration registers. A PCIe bus configuration access is used to read/write the PCIe card's configuration registers.

When the computer is first powered-up, the computer's system configuration software scans the PCIe bus to determine what PCIe devices are present. The software also determines the configuration requirements of the PCIe card.

The system software accesses the configuration registers to determine how many blocks of memory space the module requires. It then programs the board's configuration registers with the unique memory base address.

Since this board is not fixed in address space, its device driver must use the mapping information stored in the board's Configuration Space registers to determine where the board is mapped in memory space.

The configuration registers are also used to indicate that the board requires an interrupt request. The system software then programs the configuration registers with the interrupt request assigned to the board.

## CONFIGURATION REGISTERS

The PCIe specification requires software driven initialization and configuration via the Configuration Address space. This board provides 512 bytes of configuration registers for this purpose. It contains the configuration registers shown in Table 7 to facilitate Plug-and-Play compatibility.

The Configuration Registers are accessed via the Configuration Address and Data Ports. The most important Configuration Registers are the Base Address Registers and the Interrupt Register which must be read to determine the base address assigned to the board and the interrupt request that goes active on a board interrupt request.

**Table 7 Configuration Registers**

Reg. Num.	D31	D24	D23	D16	D15	D8	D7	D0
0	Device ID 0x7000 XMC-7K325F 0x7001 XMC-7K410F 0x7002 XMC-7K325AX 0x7003 XMC-7K410AX 0x7004 XMC-7K325CC 0x7005 XMC-7K410CC 0x7006 XMC-7A200 0x7007 XMC-7A200CC				Vendor ID  16D5			
1	Status				Command			
2	Class Code=118000						Rev ID=00	
3	BIST		Header		Latency		Cache	
4:5	64-bit Memory Base Address for Memory Accesses to PCIe interrupt, I/O registers, System Monitor registers, and Flash memory. 4M Space ( <b>BAR0</b> )							
6:7	64-bit Memory Base Address for access to DDR3 memory. 16M Space ( <b>BAR2</b> )							
8:10	Not Used							

11	Subsystem ID		Subsystem Vendor ID	
	0x7000 XMC-7K325F		16D5	
	0x7001 XMC-7K410F			
	0x7002 XMC-7K325AX			
	0x7003 XMC-7K410AX			
	0x7004 XMC-7K325CC			
	0x7005 XMC-7K410CC			
	0x7006 XMC-7A200			
0x7007 XMC-7A200CC				
12	Not Used			
13,14	Reserved			
15	Max_Lat	15	Max_Lat	15

This board is allocated a 4M byte block of memory (BAR0), to access the PCIe interrupt, I/O registers, XADC registers, and Flash memory. The PCIe bus decodes 4M bytes for BAR0 for this memory space.

This board is also allocated a 16M byte block of memory (BAR2), to access DDR3 memory. The PCIe bus decodes 16M bytes for BAR2 for this memory space.

## BAR0 MEMORY MAP

The BAR0 memory address space is used to access the PCIe interrupt, Front, Rear, and P16 I/O registers, System Monitor registers, and Flash memory. Note that the base address for the board (BAR0) in memory space must be added to the addresses shown to properly access these registers.

**Table 8 BAR0 Registers**

BAR0 Base Address	Size	Description
0x0000_0000→0x0000_7FFF	32K	Reserved
0x0000_8000→0x0000_8FFF	4K	AXM Module (see specific AXM model user's manual for additional address detail)
0x0000_9000→0x0009_FFFF	604K	Reserved
0x000A_0000→0x000A_FFFF	64K	<a href="#">CDMA</a> (see <a href="#">PG034</a> )
0x000B_0000→0x000E_FFFF	256K	Reserved
0x000F_0000→0x000F_FFFF	64K	<a href="#">PCIe AXI Bridge Control</a> (see <a href="#">PG054</a> )
0x0010_0000→0x0010_FFFF	64K	<a href="#">Interrupt Controller</a> (see <a href="#">PG099</a> )
0x0011_0000→0x002F_FFFF	1M	Reserved
0x0030_0000→0x0030_FFFF	64K	<a href="#">XADC System Monitor</a> (see <a href="#">DS790</a> )

BAR0 Base Address	Size	Description
0x0031_0000→0x0031_FFFF	64K	<a href="#">P1 Front I/O</a> AXI_GPIO (XMC-7Kxxx models) (see <a href="#">PG144</a> )
0x0032_0000→0x0032_FFFF	64K	<a href="#">P16 I/O</a> AXI_GPIO (see <a href="#">PG144</a> )
0x0033_0000→0x0033_FFFF	64K	<a href="#">P4 Rear I/O</a> AXI_GPIO (see <a href="#">PG144</a> )
0x0034_0000→0x0034_FFFF	64K	<a href="#">Aurora Control/Status</a> AXI_GPIO (see <a href="#">PG144</a> )
0x0035_0000→0x00FF_FFFF	12M	Reserved

Note that any registers/bits not mentioned will remain at the default value: logic low.

## CDMA MEMORY MAP

The Central Direct Memory Access (CDMA) controller can access the following devices: Flash memory, DDR3 memory, AXI to PCI bridge (BAR0), and the control registers for the PCIe interface. Note that the PCIe interface cannot directly access Flash memory; transfers to and from Flash must be initiated by the CDMA controller. The CDMA controller includes the scatter gather function. If used, the scatter gather descriptor list must be located in DDR3 memory.

BAR0 Base Address	Size	Description
0x0000_0000→0x000E_FFFF	960K	Reserved
0x000F_0000→0x000F_FFFF	64K	<a href="#">PCIe AXI Bridge Control</a> (see <a href="#">PG054</a> )
0x0010_0000→0x5FFF_FFFF	1535M	Reserved
0x6000_0000→0x63FF_FFFF	64M	<a href="#">Flash AXI EMC</a> (see <a href="#">PG100</a> )
0x6400_0000→0x7FFF_FFFF	448M	Reserved
0x8000_0000→0xBFFF_FFFF	1G	DDR3 SDRAM
0xC000_0000→0xFFFF_FFFF	1G	Reserved

## INTERRUPT CONTROLLER

The AXI Interrupt Controller concentrates multiple interrupt inputs from peripheral devices to a single interrupt output to the system processor using the PCIe bus. The interrupt controller contains programmer accessible registers that allow interrupts to be enabled, queried and cleared under software control over the PCIe bus interface.

**Table 9 Interrupt Controller Registers**

BAR0 Base Addr+	Bit(s)	Description
0x00100000	31:0	<a href="#">Interrupt Status Register</a>
0x00100004	31:0	<a href="#">Interrupt Pending Register</a>
0x00100008	31:0	<a href="#">Interrupt Enable Register</a>
0x0010000C	31:0	<a href="#">Interrupt Acknowledge Register</a>
0x00100010	31:0	<a href="#">Set Interrupt Enable Register</a>
0x00100014	31:0	<a href="#">Clear Interrupt Enable Register</a>
0x00100018	31:0	<a href="#">Interrupt Vector Register</a>
0x0010001C	31:0	<a href="#">Master Enable Register</a>

Note that any registers/bits not mentioned will remain at the default value logic low.

## Interrupt Status Register

This Interrupt Status register (ISR) at BAR0 base address + offset 0x100000 is used to monitor board interrupts. When read, the contents of this register indicate the presence or absence of an active interrupt for each of the active interrupting sources. Each bit in this register that is set to a '1' indicates an active interrupt signal on the corresponding interrupt input. Bits that are '0' are not active. The bits in the ISR are independent of the interrupt enable bits in the Interrupt Enable register. Interrupts, even if not enabled can still show up as active in the ISR.

**Table 10 Interrupt Status Register (Read/Write) - (BAR0 + 0x00100000)**

Bit(s)	FUNCTION
0	When set indicates an interrupt from either the AXM module (AXM models) or Front I/O (F Models). See the appropriate AXM module user's manual for information on the source of this interrupt.
	0 Disabled
	1 Enabled
1	When set indicates an AXI CDMA interrupt. See the CDMA section for source of this interrupt.
	0 Disabled
	1 Enabled

The ISR register is writable by software only until the Hardware Interrupt Enable bit in the MER has been set. Given these restrictions, when this

register is written to, any data bits that are set to '1' will activate the corresponding interrupt just as if a hardware input became active. Data bits that are zero have no effect. This allows software to generate interrupts for test purposes.

### Interrupt Pending Register

This Interrupt Pending register (IPR) at BAR0 base address + offset 0x100004 is used to monitor board interrupts. Reading the contents of this register indicates the presence or absence of an active interrupt signal that is also enabled. Each bit in this register is the logical AND of the bits in the Interrupt Status register and the Interrupt Enable register.

**Table 11 Interrupt Pending Register (Read) - (BAR0 + 0x00100004)**

Bit(s)	FUNCTION
0	When set indicates an interrupt from the AXM module or Front I/O. See the appropriate AXM module user's manual for information on the source of this interrupt.
	0 Disabled
	1 Enabled
1	When set indicates an AXI CDMA interrupt. See the CDMA section for source of this interrupt.
	0 Disabled
	1 Enabled
31-2	Reserved
	0 NA
	1 NA

### Interrupt Enable Register

This is a read/write register. Writing a '1' to a bit in this register enables the corresponding Interrupt Status bit to cause assertion of the interrupt output. This Interrupt Enable bit set to '0' does not inhibit an interrupt condition from being captured. It will still show up in the Interrupt Status register even when not enabled here. To show up in the Interrupt Pending register it needs to be enabled here. Writing a '0' to a bit disables, or masks, the generation of interrupt output for the corresponding interrupt input signal. Note however, that disabling an interrupt input is not the same as clearing it. Disabling an active interrupt prevents that interrupt from reaching the IRQ output. When it is re-enabled, the interrupt immediately generates a request on the IRQ output. An interrupt must be cleared by writing to the Interrupt Acknowledge Register, as described below. Reading this Interrupt Enable register indicates

which interrupt inputs are enabled; where a '1' indicates the input is enabled and a '0' indicates the input is disabled.

**Table 12 Interrupt Enable Register (Read/Write) - (BAR0 + 0x00100008)**

Bit(s)	FUNCTION
0	When set indicates an interrupt from AXM module or Front I/O is enabled. See the appropriate AXM module data sheet for information on the source of this interrupt.
	0 Disabled
	1 Enabled
1	When set indicates an AXI CDMA interrupt enable. See the CDMA section for source of this interrupt.
	0 Disabled
	1 Enabled
31-2	Reserved
	0 NA
	1 NA

### Interrupt Acknowledge Register

The Interrupt Acknowledge register is a write-only location that clears the interrupt request associated with selected interrupt inputs. Note that writing one to a bit in Interrupt Acknowledge register clears the corresponding bit in Interrupt Status register, and also clears the same bit itself in the Interrupt Acknowledge register.

Writing a '1' to a bit location in the Interrupt Acknowledge register will clear the interrupt request that was generated by the corresponding interrupt input. An interrupt input that is active and masked by writing a '0' to the corresponding bit in the Interrupt Enable register will remain active until cleared by acknowledging it. Unmasking an active interrupt causes an interrupt request output to be generated (if the Master Interrupt Enable bit-0 in the Master Enable register is set). Writing 0s has no effect as does writing a '1' to a bit that does not correspond to an active input or for which an interrupt input does not exist. The bit locations in the Interrupt Acknowledge register correspond with the bit locations given in the Interrupt Enable register Table.

**Table 13 Interrupt Acknowledge Register (Write) - (BAR0 + 0x0010000C)**

Bit(s)	FUNCTION
0	Clear AXM / Front I/O interrupt request.
1	Clear AXI CDMA interrupt request.
31-2	Reserved

### Set Interrupt Enable Register

Set Interrupt Enable register is a location used to set Interrupt Enable register bits in a single atomic operation, rather than using a read / modify / write

sequence. Writing a '1' to a bit location in the Set Interrupt Enable register will set the corresponding bit in the Interrupt Enable register. Writing 0s does nothing, as does writing a '1' to a bit location that corresponds to a non-existing interrupt input. The bit locations in the Set Interrupt Enable correspond with the bit locations given in the Interrupt Enable register Table.

**Table 14 Set Interrupt Enable Register (Write) - (BAR0 + 0x00100010)**

Bit(s)	FUNCTION
0	Set AXM/Front I/O interrupt enable.
1	Set AXI CDMA interrupt enable.
31-2	Reserved

### Clear Interrupt Enable Register

Clear Interrupt Enable register is a location used to clear Interrupt Enable register bits in a single atomic operation, rather than using a read / modify / write sequence. Writing a '1' to a bit location in Clear Interrupt Enable register will clear the corresponding bit in the Interrupt Enable register. Writing 0s does nothing, as does writing a '1' to a bit location that corresponds to a non-existing interrupt input. The bit locations in the clear Interrupt Enable correspond with the bit locations given in the Interrupt Enable register Table.

**Table 15 Clear Interrupt Enable Register (Write) - (BAR0 + 0x00100014)**

Bit(s)	FUNCTION
0	Clear AXM/Front I/O interrupt enable.
1	Clear AXI CDMA interrupt enable.
31-2	Reserved

### Interrupt Vector Register

The Interrupt Vector register is a read-only register and contains the ordinal value of the highest priority, enabled, and active interrupt input. INTO (always the LSB) is the highest priority interrupt input. Each successive input (to the left) has a corresponding lower interrupt priority. If no interrupt inputs are active, the Interrupt Vector register contains all 1s. This Interrupt Vector register acts as an index for giving the correct Interrupt Vector Address.

**Table 16 Interrupt Vector Register (Read) - (BAR0 + 0x00100018)**

Bit(s)	FUNCTION
31-0	Ordinal value of the highest priority enabled active interrupt, 0xFFFFFFFF if no interrupt inputs are active

### Master Enable Register

This is a 2-bit, read / write register. The two bits are mapped to the two least significant bits of the location. The least significant bit contains the Master Enable bit and the next bit contains the Hardware Interrupt Enable bit. Writing a '1' to the Master Enable bit enables the IRQ output signal. Writing a

'0' to the Master Enable bit disables the IRQ output, effectively masking all interrupt inputs. The Hardware Interrupt Enable bit is a write-once bit. At reset, this bit is reset to '0', allowing the software to write to the Interrupt Status register to generate interrupts for testing purposes, and disabling any hardware interrupt inputs. Writing a '1' to this bit enables the hardware interrupt inputs and disables software generated inputs. Writing a '1' also disables any further changes to this bit until the device has been reset. Writing 1s or 0s to any other bit location does nothing. When read, this register will reflect the state of the Master Enable and Hardware Interrupt Enable bits. All other bits will read as 0s.

**Table 17 Master Enable Register (Read/Write) - (BAR0 + 0x0010001C)**

Bit(s)	FUNCTION	
0	Master IRQ Enable	
	0	All Interrupts Disabled
	1	All Interrupts Enabled
1	Hardware Interrupt Enable	
	0	Software Interrupts Enabled
	1	Hardware Interrupts Only Enabled
31-2	Not Used (bits are read as logic "0")	

## AXI-CDMA

The AXI Central Direct Memory Access (CDMA) core is a soft Xilinx Intellectual Property core. The CDMA provides direct memory access between system memory over the PCIe bus and the memory resident on the XMC-7 series module.

The basic mode of operation for the CDMA is Simple DMA. In this mode, the CDMA executes one programmed DMA command and then stops. This requires that the CDMA registers need to be set up by system software over the PCIe bus for each DMA operation required.

Scatter Gather is a mechanism that allows for automated DMA transfer scheduling via a pre-programmed instruction list of transfer descriptors (Scatter Gather Transfer Descriptor Definition). This instruction list is programmed by the user software application into a memory-resident data structure that must be accessible by the AXI CDMA Scatter Gather interface. This list of instructions is organized into what is referred to as a transfer descriptor chain. Each descriptor has an address pointer to the next descriptor to be processed. The last descriptor in the chain generally points back to the first descriptor in the chain but it is not required. The AXI CDMA Tail Descriptor Pointer register needs to be programmed with the address of the first word of the last descriptor of the chain. When the AXI CDMA executes the last descriptor and finds that the Tail Descriptor pointer matches the address of the completed descriptor, the Scatter Gather Engine stops descriptor fetching and waits. See the Xilinx AXI Central Direct Memory

Access product guide [PG034](#) for additional details for Scatter Gather operations.

**Table 18 AXI CDMA Registers**

BAR0 Base Addr+	Bit(s)	Description
0x000A0000	31:0	<a href="#">CDMA Control Register</a>
0x000A0004	31:0	<a href="#">CDMA Status Register</a>
0x000A0008	31:0	<a href="#">Current Descriptor Pointer Register</a>
0x000A000C	31:0	Reserved
0x000A0010	31:0	<a href="#">Tail Descriptor Pointer Register</a>
0x000A0014	31:0	Reserved
0x000A0018	31:0	<a href="#">Source Address Register</a>
0x000A001C	31:0	Reserved
0x000A0020	31:0	<a href="#">Destination Address Register</a>
0x000A0024	31:0	Reserved
0x000A0028	31:0	<a href="#">Bytes to Transfer Register</a>

Note that any registers/bits not mentioned will remain at the default value: logic low.

### CDMA Control Register

This register provides software application control of the AXI CDMA.

**Table 19 CDMA Control Register (Read/Write) - (BAR0 + 0x000A0000)**

Bit(s)	FUNCTION
0	This bit is reserved for future definition and will always return zero.
1	Indicates tail pointer mode is enabled to the Scatter Gather Engine. This bit is fixed to 1 and always read as 1 when Scatter Gather is included. If the CDMA is built with Scatter Gather disabled (Simple Mode Only), the default value of the port is 0.
0	Tail Pointer Mode is Disabled
1	Tail Pointer Mode is Enabled
2	Soft reset control for the AXI CDMA core. Setting this bit to a '1' causes the AXI CDMA to be reset. Reset is accomplished gracefully. Committed AXI4 transfers are then completed. Other queued transfers are flushed. After completion of a soft reset, all registers and bits are in the Reset State.
0	Reset Not in Progress

Bit(s)	FUNCTION
1	Reset in Progress
3	<p>This bit controls the transfer mode of the CDMA. Setting this bit to a '1' causes the AXI CDMA to operate in a Scatter Gather mode.</p> <p><b>Note:</b> This bit must only be changed when the CDMA engine is IDLE (CDMA Status bit-1 = '1'). Changing the state of this bit at any other time has undefined results.</p> <p><b>Note:</b> This bit must be set to a 0 then back to 1 by the software application to force the CDMA Scatter Gather engine to use a new value written to the CDMA Current Descriptor Pointer register.</p> <p><b>Note:</b> This bit must be set prior to setting Bit-13 of this CDMA Control register.</p>
0	Simple DMA Mode
1	Scatter Gather Mode
11-4	Reserved
12	<p>Interrupt on Complete Interrupt Enable. When set to '1', it allows an interrupt after completed DMA transfers.</p>
0	Interrupt on Complete Disabled
1	Interrupt on Complete Enabled
13	<p>Interrupt on Delay Timer Interrupt Enable. When set to '1', it allows a delayed interrupt out. This is only used with Scatter Gather assisted transfers.</p>
0	Delayed Interrupt Disabled
1	Delayed Interrupt Enabled
14	<p>Interrupt on Error Interrupt Enable. When set to '1', it allows an error to generate an interrupt out.</p>
0	Error Interrupt Disabled
1	Error Interrupt Enabled
15	Reserved
23-16	<p>Interrupt Threshold value. This field is used to set the Scatter Gather interrupt coalescing threshold. When Interrupt On Complete interrupt events occur, an internal counter counts down from the Interrupt Threshold setting. When the count reaches zero, an interrupt out is generated by the CDMA engine.</p> <p><b>Note:</b> The minimum setting for the threshold is 0x01. A write of 0x00 to this register has no effect. If the CDMA is built with Scatter Gather disabled (Simple Mode Only), the default value of the port is zeros.</p>

Bit(s)	FUNCTION
31-24	<p>Interrupt Delay Time Out. This value is used for setting the interrupt delay time out value. The interrupt time out is a mechanism for causing the CDMA engine to generate an interrupt after the delay time period has expired. This is used for cases when the interrupt threshold is not met after a period of time, and the CPU desires an interrupt to be generated. Timer begins counting when the CDMA is IDLE (CDMA Status bit-1 = '1'). This generally occurs when the CDMA has completed all scheduled work defined by the transfer descriptor chain (reached the tail pointer) and has not satisfied the Interrupt Threshold count.</p> <p><b>Note:</b> Setting this value to zero disables the delay timer interrupt.</p>

### CDMA Status Register

This register provides status of the AXI CDMA.

**Table 20 CDMA Status Register (Read/Write) - (BAR0 + 0x000A0004)**

Bit(s)	FUNCTION				
0	This bit is reserved for future definition and will always return zero.				
1	<p>CDMA Idle. Indicates the state of AXI CDMA operations. When set and in Simple DMA mode, the bit indicates the programmed transfer has completed and the CDMA is waiting for a new transfer to be programmed. Writing to the "Bytes to Transfer" register in Simple DMA mode causes the CDMA to start (not Idle).</p> <p>When set and in Scatter Gather mode, the bit indicates the Scatter Gather Engine has reached the tail pointer for the associated channel and all queued descriptors have been processed. Writing to the tail pointer register automatically restarts CDMA Scatter Gather operations.</p> <table> <tr> <td>0</td><td>Not Idle</td></tr> <tr> <td>1</td><td>CDMA is Idle</td></tr> </table>	0	Not Idle	1	CDMA is Idle
0	Not Idle				
1	CDMA is Idle				
2	Reserved				
3	<p>Scatter Gather Included. This bit indicates if the AXI CDMA has been implemented with Scatter Gather support included (C_SG_ENABLE = 1). This is used by application software (drivers) to determine if Scatter Gather Mode can be utilized.</p> <table> <tr> <td>0</td><td>Scatter Gather not included</td></tr> <tr> <td>1</td><td>Scatter Gather is included</td></tr> </table>	0	Scatter Gather not included	1	Scatter Gather is included
0	Scatter Gather not included				
1	Scatter Gather is included				

Bit(s)	FUNCTION
4	DMA Internal Error. This bit indicates that an internal error has been encountered by the DataMover on the data transport channel. This error can occur if a 0 value Byte to Transfer register is fed to the AXI DataMover or DataMover has an internal processing error. A Bytes to Transfer register value of 0 only happens if the register is written with zeros (in Simple DMA mode) or a Bytes to Transfer register value of zero is specified in the Control word of a fetched descriptor is set to 0 (Scatter Gather Mode). This error condition causes the AXI CDMA to gracefully halt. The CDMA Status register bit-1 is set to '1' when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No CDMA Internal Errors
	1 CDMA Internal Error detected. CDMA Engine halts.
5	DMA Slave Error. This bit indicates that an AXI slave error response has been received by the AXI DataMover during an AXI transfer (read or write). This error condition causes the AXI CDMA to gracefully halt. The CDMA Status register bit-1 is set to '1' when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No CDMA Slave Errors
	1 CDMA Slave Error detected. CDMA Engine halts.
6	DMA Decode Error. This bit indicates that an AXI decode error has been received by the AXI DataMover. This error occurs if the DataMover issues an address that does not have a mapping assignment to a slave device. This error condition causes the AXI CDMA to halt gracefully. The CDMA Status register bit-1 is set to '1' when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No CDMA Decode Errors
	1 CDMA Decode Error detected. CDMA Engine halts.
7	Reserved
8	Scatter Gather Internal Error. This bit indicates that an internal error has been encountered by the Scatter Gather Engine. This error condition causes the AXI CDMA to gracefully halt. The CDMA Status register bit-1 is set to 1 when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No Scatter Gather Internal Errors
	1 Scatter Gather Internal Error. CDMA Engine halts.

Bit(s)	FUNCTION
9	Scatter Gather Slave Error. This bit indicates that an AXI slave error response has been received by the Scatter Gather Engine during an AXI transfer (transfer descriptor read or write). This error condition causes the AXI CDMA to gracefully halt. The CDMA Status register bit-1 is set to 1 when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No Scatter Gather Slave Errors
	1 Scatter Gather Slave Error. CDMA Engine halts.
10	Scatter Gather Decode Error. This bit indicates that an AXI decode error has been received by the Scatter Gather Engine during an AXI transfer (transfer descriptor read or write). This error occurs if the Scatter Gather Engine issues an address that does not have a mapping assignment to a slave device. This error condition causes the AXI CDMA to gracefully halt. The CDMA Status register bit-1 is set to 1 when the CDMA has completed shut down. A reset (soft or hard) must be issued to clear the error condition.
	0 No Scatter Gather Decode Errors
	1 Scatter Gather Decode Error. CDMA Engine halts.
11	Reserved
12	Interrupt on Complete. When set to 1, this bit indicates an interrupt event has been generated on completion of a DMA transfer (either a Simple or Scatter Gather). If the Interrupt on Complete (bit-12) of the CDMA Control register = '1', an interrupt is generated from the AXI CDMA. A CPU write of 1 clears this bit to 0. <b>Note:</b> When operating in Scatter Gather mode, the criteria specified by the interrupt threshold must also be met.
	0 No IOC Interrupt
	1 IOC Interrupt active
13	Interrupt on Delay. When set to 1, this bit indicates an interrupt event has been generated on a delay timer time out. If the Interrupt on Delay Timer bit-13 of the CDMA Control register = '1', an interrupt is generated from the AXI CDMA. A CPU write of 1 clears this bit to 0.
	0 No Delay Interrupt
	1 Delay Interrupt Active
14	Interrupt on Error. When set to 1, this bit indicates an interrupt event has been generated due to an error condition. If the Interrupt on Error bit-14 of the CDMA Control register = '1', an interrupt is generated from the AXI CDMA. A CPU write of 1 clears this bit to 0.
	0 No Error Interrupt
	1 Error Interrupt Active
15	Reserved

Bit(s)	FUNCTION
23-16	Interrupt Threshold Status. This field reflects the current interrupt threshold value in the Scatter Gather Engine.
31-24	Interrupt Delay Time Status. This field reflects the current interrupt delay timer value in the Scatter Gather Engine.

### CDMA Current Descriptor Pointer Register

**Table 21 CDMA Current Descriptor Pointer Register (Read/Write) - (BAR0 + 0x000A0008)**

Bit(s)	FUNCTION
5-0	Writing to these bits has no effect and they are always read as zeros.
31-6	<p>Current Descriptor Pointer. This register field is written by the software application (in Scatter Gather Mode) to set the starting address of the first transfer descriptor to execute for a Scatter Gather operation. The address written corresponds to a 32-bit system address with the least significant 6 bits truncated. This register field must contain a valid descriptor address prior to the software application writing the CDMA Tail Descriptor Pointer register value. Failure to do so results in an undefined operation by the CDMA.</p> <p>On error detection, the Current Descriptor Pointer register is updated to reflect the descriptor associated with the detected error.</p> <p><b>Note:</b> The register should only be written by the Software application when the AXI CDMA is Idle.</p>

### CDMA Tail Descriptor Pointer Register

This register provides Tail Descriptor Pointer for the AXI CDMA Scatter Gather Descriptor Management.

**Table 22 CDMA Tail Descriptor Pointer Register (Read/Write) - (BAR0 + 0x000A0010)**

Bit(s)	FUNCTION
5-0	Writing to these bits has no effect and they are always read as zeros.
31-6	<p>Tail Descriptor Pointer. This register field is written by the software application (in Scatter Gather Mode) to set the current pause pointer for descriptor chain execution. The AXI CDMA Scatter Gather Engine pauses descriptor fetching after completing operations on the descriptor whose current descriptor pointer matches the tail descriptor pointer. When the AXI CDMA is in Scatter Gather Mode, a write by the software application to this register causes the AXI CDMA Scatter Gather Engine to start fetching descriptors starting from the Current Descriptor Pointer register value. If the Scatter Gather engine is paused at a tail pointer pause point, the Scatter Gather engine restarts descriptor execution at the next sequential transfer descriptor. If the AXI CDMA is not idle, writing to this register has no effect except to reposition the Scatter Gather pause point.</p> <p><b>Note:</b> The software application must not move the tail pointer to a location that has not been updated with valid transfer descriptors. The software application must process and reallocate all completed descriptors, clear the completed bits and then move the tail pointer. The software application must move the pointer to the last descriptor address it has updated.</p>

### CDMA Source Address Register

This register provides the source address for simple DMA transfers by AXI CDMA.

If a location in system memory is the source address, it must be set with the AXI aperture base address 0x01000000 + the least significant 24-bits of the system memory address.

In addition, the physical address of the location in system memory must be set in the Address Translation Register which is described in the PCIe AXI-Bridge Control section.

**Table 23 CDMA Source Address Register (Read/Write) - (BAR0 + 0x000A0018)**

Bit(s)	FUNCTION
31-0	Source Address Register. This register is used by Simple DMA operations as the starting read address for DMA data transfers. The address value written can be at any byte offset. <b>Note:</b> The software application should only write to this register when the AXI CDMA is Idle.

### CDMA Destination Address Register

This register provides the destination address for simple DMA transfers by AXI CDMA.

If a location in system memory is the destination address, it must be set with the AXI aperture base address 0x01000000 + the least significant 24-bits of the system memory address.

In addition, the physical address of the location in system memory must be set in the Address Translation Register which is described in the PCIe AXI-Bridge Control section.

**Table 24 CDMA Destination Address Register (Read/Write) - (BAR0 + 0x000A0020)**

Bit(s)	FUNCTION
31-0	Destination Address Register. This register is used by Simple DMA operations as the starting write address for DMA data transfers. <b>Note:</b> The software application should only write to this register when the AXI CDMA is Idle.

## CDMA Bytes to Transfer Register

This register provides the value for the bytes to transfer for Simple DMA transfers by the AXI CDMA.

**Table 25 CDMA Bytes to Transfer Register (Read/Write) - (BAR0 + 0x000A0028)**

Bit(s)	FUNCTION
22-0	Bytes to Transfer. This register field is used for Simple DMA transfers and indicates the desired number of bytes to DMA from the Source Address to the Destination Address. A maximum of 8,388,606 bytes of data can be specified by this field for the associated transfer. <b>Writing to this register also initiates the Simple DMA transfer.</b> Note: A value of zero (0) is not allowed and causes a DMA internal error to be set by AXI CDMA. The software application should only write to this register when the AXI CDMA is Idle.
31-23	Writing to these bits has no effect, and they are always read as zeros.

## Simple CDMA Programming Example

1. Verify the CDMA is idle. Read CDMA Status register bit-1 as logic '1'.
2. Program the CDMA Control register bit-12 to the desired state for interrupt generation on transfer completion.
3. Write the desired transfer source address to the Source Address register at 0xA0018. The transfer data at the source address must be valid and ready for transfer. If we were to select the DDR memory as the source and wanted to start a move of data from the beginning of DDR, we would write 0x80000000 to the Source Address register at 0xA0018.
4. Write the desired transfer destination address to the Destination Address register at 0xA0020. If the destination is the system memory then the following is required.
  - a. Given physical address of buffer of 0x0000333012345678
  - b. AXIBAR2PCIEBAR\_OU <offset 000F0208> = 0x00003330
  - c. AXIBAR2PCIEBAR\_OL <offset 000F020C> = 0x12345678
  - d. The least significant 24 bits of this address 0x12345678 must be removed and added to the AXI BAR0 Aperture Base address. The new AXI address is 0x01000000 + 0x00345678 = 0x01345678. Write 0x01345678 to 0xA0020.
5. Write the number of bytes to transfer to the CDMA Bytes to Transfer register 0xA0028. Writing this register also starts the transfer.
6. Either poll the CDMA Status register bit-1 for logic '1' or wait for the CDMA to generate an interrupt if enabled.

7. Clear the interrupt if generated by writing a '1' to bit-12 of the CDMA Status register.
8. Ready for another transfer. Go back to step 1.

### AXI-BAR0 Aperture Base Address

The AXI BAR0 aperture base address of 0x01000000 is set as the base address on the AXI bus used to reach system host memory for CDMA transfers.

The address 0x01000000 is the AXI BAR0 Aperture Base address. In Vivado IP Integrator the address map will show that a 16Meg address space for the AXI BAR0 Aperture Base Address is reserved.

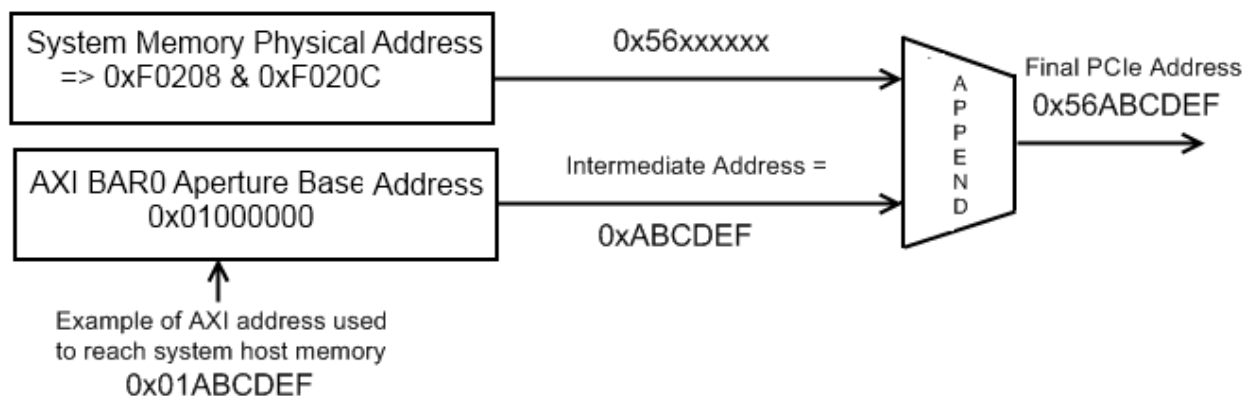

**Table 26 AXI BAR0 Aperture Base Address**

<b>0x01000000→0x01FFFFFF</b>	16M	Window into PCIe Interface AXI BAR0 Aperture Base Address
------------------------------	-----	--

The following is an example of how the AXI BAR0 aperture base address is used.

For example if the system buffer physical address 0x56ABCDEF were given, then the AXI Base Address Translation Configuration registers at BAR0 + 0xF0208 and 0xF020C must be set to 0x0 and 0x56 ABCDEF respectively.

The least significant 24 bits of this address 0x56ABCDEF must be removed and added to the AXI BAR0 Aperture Base address. The new AXI address is  $0x01000000 + 0x00ABCDEF = 0x01ABCDEF$ . These values are then appended by the PCIe AXI bridge to give the final PCIe address of the system memory location.

### PCIe AXI-Bridge Control

The PCIe AXI Bridge is an interface between the AXI bus and the PCIe. This bridge provides the address translation between the AXI4 memory-mapped embedded system and the PCIe system. The AXI Bridge for PCIe translates the AXI memory read or writes to PCIe Transaction Layer Packets (TLP)

packets and translates PCIe memory read and write request TLP packets to AXI interface commands.

**Table 27 PCIe AXI Bridge Control Registers**

BAR0 Base Addr+	Bit(s)	Description
0x000F0000→ 0x000F0140	31:0	See Xilinx <a href="#">pg055</a> Memory Map
0x000F0144	31:0	<a href="#">PHY Status/Control Register</a>
0x000F0148→ 0x000F0204	31:0	See Xilinx <a href="#">pg055</a> Memory Map
0x000F0208	31:0	<a href="#">Address Translation Register Upper</a> AXIBAR2PCIEBAR_OU
0x000F020C	31:0	Address Translation Register Lower AXIBAR2PCIEBAR_OL
0x000F0210→ 0x000F0FFF	31:0	See Xilinx <a href="#">pg055</a> Memory Map

### PHY Status/Control Register

This register provides the status of the current PHY state, as well as control of speed and rate switching for Gen2-capable cores.

**Table 28 PHY Status/Control Register (Read/Write) - (BAR0 + 0x000F0144)**

Bit(s)	FUNCTION	
0	Reports the current link rate.	
	0	2.5 GT/s
	1	5.0 GT/s
2-1	Reports the current link width.	
	00	x1
	01	x2
	10	x4
	11	x8
8-3	Reports the current Link Training and Status State Machine state. Encoding is specific to the underlying Integrated Block.	
	x	
	x	
10-9	Reports the current lane reversal mode.	
	00	No reversal
	01	Lanes 1:0 reversed
	10	Lanes 3:0 reversed
	11	Lanes 7:0 reversed
11	Reports the current PHY Link-up state.	
	0	Link down

Bit(s)	FUNCTION
1	Link up
15-12	Reserved
31-16	See Xilinx <a href="#">pg055</a> PHY Status/Control Register

### AXI Base Address Translation Configuration Register

The address space for PCIe is different than the AXI address space. To access one address space from another address space requires an address translation process.

These register are needed for DMA transfers that move data to the system memory buffer. The location of the system memory buffer is loaded into these registers.

AXI Base Address Translation Configuration register at BAR0 + 0xF0208 must be written with the most significant 32 bits of the address in system memory to which the DMA transfer is to read or write. An example of the c code used to set this register with the physical address is shown below.

AXI Base Address Translation Configuration register at BAR0 + 0xF020C must be written with the least significant 32 bits of the address in system memory to which the DMA transfer is to read or write. An example of the c code used to set this register with the physical address is shown below.

#### Example C code:

```
#define AXI2PCleBAR_OU      (*(DWORD*)(u64BaseAddress + 0xF0208))
#define AXI2PCleBAR_OL      (*(DWORD*)(u64BaseAddress + 0xF020C))

iStatus = PCIe7K_DmaGetBuffPhysAddress(iHandle, &u64PhyAddr);

AXI2PCleBAR_OU = (DWORD)(u64PhyAddr >> 32);
AXI2PCleBAR_OL = (DWORD)(u64PhyAddr & 0xffffffff);
```

This sets the system memory physical address which will be appended with the values written into either the DMA source or destination registers at 0xA0018 or 0xA0020 respectively. See the example in the CDMA section for additional details.

### Aurora Status

The Aurora Status register is used to monitor eight Aurora loopback lanes that are on the P16 connector. The XMC module must be installed on a carrier that has a P16 loopback cable connected to enable the channels to connect. This Aurora Monitor register is accessed at base address plus 0x340000. The Aurora Monitor register bit-0 is used take the Aurora link into and out of reset. Set to logic '1' the link is held in reset and set to logic '0' the link is removed from reset.

**Table 29 Aurora Status Register (Read) – (BAR0 + 0x340000)**

Bit(s)	Function
0	Aurora Reset Control:
	0 Removed from Reset
	1 Held in Reset
1	Reserved
2	Channel UP
	0 Loopback Channel is down
	1 Loopback Channel is up
3-15	Reserved
16-23	Link
	0 Link is down
	1 Link is up
24-31	Reserved
	0 Write logic low has no effect
	1 Write logic high has no effect

## Control Register

This Control register provides a single output signal. It is accessed at base address plus 0x340008. The Control register bit-0 is used take the Aurora link into and out of reset. Set to logic '1' the link is held in reset and set to logic '0' the link is removed from reset.

**Table 30 Aurora Control Register (Read/Write) – (BAR0 + 0x340008)**

Bit(s)	Function
0	Aurora Reset Control:
	0 Removed from Reset
	1 Held in Reset
1-31	Reserved
	0 Write logic low has no effect
	1 Write logic high has no effect

## Flash Memory

The BPI flash memory provides 64M bytes of non-volatile memory for storing the FPGA configuration bitstream and program code or data storage for an embedded MicroBlaze processor.

The system CPU cannot directly access the flash memory. The CDMA controller must be used to transfer data between DDR3 memory and Flash. The system CPU must first write/read data to/from DDR3 memory and then initiate a DMA transfer to move the data to/from Flash memory. The CDMA controller must also be utilized to read/write Flash memory control and status registers.

The BPI flash device is organized as eight 64-Mbit partitions. See Table 31 below. Each partition contains 32 Blocks. Each block contains 256K bytes. The FPGA bitstream occupies partitions 0 and 1. XMC-7A200/CC models are

delivered with a duplicate copy of the FPGA example bitstream stored in partitions 2 and 3. The flash memory is a 16 bit device; it does not support single byte accesses. Note: The Flash memory includes One-Time Programmable (OTP) blocks. Acromag writes the protection bits for these blocks during factory programming to disable this feature.

**Table 31 Flash Memory Map (Read/Write) – (BAR0 + 0x60000000)**

Partition	Block #	Address Range(word addresses)
7	255	63FC0000 - 63FFFFFF
	⋮	⋮
	224	63800000 - 6383FFFF
6	223	637C0000 - 637FFFFFF
	⋮	⋮
	192	63000000 - 6303FFFF
5	191	62FC0000 - 62FFFFFF
	⋮	⋮
	160	62800000 - 6283FFFF
4	159	627C0000 - 627FFFFFF
	⋮	⋮
	128	62000000 - 6203FFFF
3	127	61FC0000 - 61FFFFFF
	⋮	⋮
	96	61800000 - 6183FFFF
2	95	617C0000 - 617FFFFFF
	⋮	⋮
	64	61000000 - 6103FFFF
1	63	60FC0000 - 60FFFFFF

Partition	Block #	Address Range(word addresses)
0	⋮	⋮
	32	60800000 - 6083FFFF
	31	607C0000 - 607FFFFF
	⋮	⋮
	0	60000000 - 6003FFFF

### Write Protected Bitstream XMC-7A200/CC Models only

XMC-7A200/CC Modes are shipped from the factory with two copies of the Acromag example design firmware stored in flash memory. Each firmware image occupies two partitions. The image stored in partitions 2 and 3 is intended to be replaced by the user's custom firmware. The image stored in partitions 0 and 1 is write protected by the example design firmware.

**Table 32 XMC-7A200/CC Flash Memory Map**

Partitions	Address Range(word addresses)
6-7	Available for user data storage
4-5	Not accessible
2-3	User Bitstream
0-1	Golden Bitstream

This write protected image can be relied upon to always configure the FPGA with a functioning PCI express interface that will allow the host to overwrite the customer's firmware stored in the second two partitions. Switch SW1 position 4 selects the bitstream that will be loaded into the FPGA after the next power cycle. Switch SW1 position 4 in the on state selects the write-protected golden configuration bitstream. SW1 position 4 in the off state selects the user modifiable configuration bitstream. Note: With SW1 position 4 in the off state and flash address line A23 unconditionally driven high, as is done in the Acromag example design, partitions 4 and 5 of the flash memory are not accessible. The golden bitstream can be overwritten by placing SW1 position 4 in the on state and writing the flash via the Xilinx Platform USB II cable. The user configuration bitstream, stored in partitions 2 and 3 can also

be written via the Xilinx Platform USB II cable by placing SW1 position 4 in the off state and writing the flash via the Xilinx Platform USB II cable.

**Table 33 Bitstream Select/Flash Write Protect Switch**

Switch SW1 Position	Function	Default Position
1	not used	off
2	not used	off
3	not used	off
4	on – select golden bitstream off – select user bitstream	off

### AXI XADC Analog to Digital Converter (System Monitor)

The XADC Analog to Digital Converter is used to monitor the die temperature and supply voltages of the FGPA. The XADC channel sequencer is configured to continuously sample the temperature, Vccint and Vccaux channels. The results from the A/D conversions can be read at the addresses given in column one of Table 34.

Data bits 15 to 4 of these registers hold the “ADCcode” representing the temperature, Vccint, or Vccaux value. Data bits 3 to 0 are not used.

The 12-bits output from the ADC can be converted to temperature using the following equation.

$$Temperature(^{\circ}C) = \frac{ADCcode \times 503.975}{4096} - 273.15$$

The 12-bits output from the ADC can be converted to voltage using the following equation.

$$SupplyVoltage(volts) = \frac{ADCcode}{4096} \times 3V$$

Additional information regarding the XADC can be found in the Xilinx XADC product guide [PG099](#) and the user guide [UG480](#)

**Table 34 System Monitor Register Map – (BAR0 + 0x3002xx)**

Address	Status Register
0x00300200	Temperature
0x00300204	Vccint
0x00300208	Vccaux
0x00300280	Maximum Temperature
0x00300284	Maximum Vccint
0x00300288	Maximum Vccaux
0x00300290	Minimum Temperature
0x00300294	Minimum Vccint
0x00300298	Minimum Vccaux

**P1 Front I/O (XMC-7K325F and XMC-7K410F models only)**

The front I/O in the provided example design has been configured as 13 LVCMOS inputs and 13 LVCMOS outputs. It can also be configured as 11 differential channels with 2 global clock signal pairs. It is an instance of Xilinx's LogiCORE IP AXI GPIO. The Xilinx IP core has been configured as follows:

GPIO channel 1 – width 13, all inputs  
 GPIO channel 2 – width 13, all outputs  
 interrupts enabled.

**P1 Front Input Data Register**

The front input data register is used to access the individual input signals. The front input includes 13 LVCMOS single ended signals. Table 35 shows the bit position assignments for each of the signals.

Input signal levels are determined by reading this register. Output signals are set by writing to the front output data register at base address plus 0x310008.

This front input data register is a read only register. Channel read operations can use 32-bit, 16-bit or 8-bit data transfers.

**Table 35 P1 Front Input Data Register - (BAR0 + 0x310000)**

Register Bit	VHDL Name	Schematic Name
0	FI(0)	FIO0_N
1	FI(1)	FIO1_N
2	FI(2)	FIO2_N
3	FI(3)	FIO3_N
4	FI(4)	FIO4_N
5	FI(5)	FIO5_N
6	FI(6)	FIO6_N
7	FI(7)	FIO7_N
8	FI(8)	FIO8_N
9	FI(9)	FIO9_N
10	FI(10)	FIO10_N
11	FI(11)	FIO11_GCLK_N
12	FI(12)	FIO12_GCLK_N

### P1 Front Output Data Register

The front output data register is used to control the 13 LVCMOS output signals. Each signal is controlled by a corresponding data bit as shown in Table 36.

P1 output signals are controlled by writing this register. P1 input signals are accessed by reading the front input data register at base address plus 0x310000.

This front output data register is a read/writable register. Channel operations use 32-bit, 16-bit or 8-bit data transfers.

**Table 36 P1 Front Output Data Register - (BAR0 + 0x310008)**

Register Bit	VHDL Name	Schematic Name
0	FO(0)	FIO0_P
1	FO(1)	FIO1_P
2	FO(2)	FIO2_P
3	FO(3)	FIO3_P
4	FO(4)	FIO4_P
5	FO(5)	FIO5_P
6	FO(6)	FIO6_P
7	FO(7)	FIO7_P
8	FO(8)	FIO8_P
9	FO(9)	FIO9_P
10	FO(10)	FIO10_P
11	FO(11)	FIO11_GCLK_P
12	FO(12)	FIO12_GCLK_P

### P1 Front Input Global Interrupt Enable Register

This register provides the master enable/disable for the P1 Front I/O interrupt output to the Interrupt Controller.

**Table 37 Front Input Global Interrupt Enable Register - (BAR0 + 0x31011C)**

Bit(s)	Front Input Global Interrupt Enable Register
0-30	Reserved
31	Front Input interrupt enable
	0 Interrupt disabled
	1 Interrupt enabled

### P1 Front Input Channel Interrupt Enable Register

The Channel Interrupt Enable Register shown in Table 38, provides a second interrupt enable bit for the input channel. (Bit 1 is reserved since Channel 2 is configured as output only)

**Table 38 Front Input Channel Interrupt Enable Register - (BAR0 + 0x310128)**

Bit(s)	Front Input Channel Interrupt Enable
0	Channel 0 interrupt enable
	0 Interrupt disabled
	1 Interrupt enabled
1-31	Reserved

### P1 Front Input Channel Interrupt Status Register

The Channel Interrupt Status Register shown in Table 39, indicates the interrupt status for the input channel. This bit is set when any of the 13 inputs change state. This bit implements Toggle-On-Write (TOW) access. The status of the bit toggles when a value of 1 is written to it.

**Table 39 Front Input Channel Interrupt Status Register - (BAR0 + 0x310120)**

Bit(s)	Front I/O Channel Interrupt Status Register
0	Channel 0 interrupt status
	0 Interrupt not active
	1 Interrupt active
1-31	Reserved

### P4 Rear Input Data Register

The rear input data register is used to access the individual input channels. The rear input includes 32 LVCMOS single ended channels. Each channel is controlled by a corresponding data bit as shown in the P4 Rear Output Data Register.

Channel input signal levels are determined by reading this register. Channel output signals are set by writing to the rear output data register at base address plus 0x330008.

This rear input data register is a read only register. Channel read operations use 32-bit, 16-bit or 8-bit data transfers. All channels of this register are fixed as input channels.

The rear I/O can also be configured as differential channels with 2 global clock signal pairs.

**Table 40 BAR0 Rear Input Data Register (Read Only) - (BAR0 + 0x330000)**

Register Bit	Channel	VHDL Name	Schematic Name
0	0	RI(0)	RIO0_GCLK_P
1	1	RI(1)	RIO1_P
2	2	RI(2)	RIO2_P
3	3	RI(3)	RIO3_P
4	4	RI(4)	RIO4_P
5	5	RI(5)	RIO5_P
6	6	RI(6)	RIO6_P
7	7	RI(7)	RIO7_P
8	8	RI(8)	RIO8_P

21	21	RI(21)	RIO21_P
22	22	RI(22)	RIO22_P
23	23	RI(23)	RIO23_P
24	24	RI(24)	RIO24_P
25	25	RI(25)	RIO25_P
26	26	RI(26)	RIO26_P
27	27	RI(27)	RIO27_P
28	28	RI(28)	RIO28_P
29	29	RI(29)	RIO29_P
30	30	RI(30)	RIO30_P
31	31	RI(31)	RIO31_GCLK_P

Note that any registers/bits not mentioned will remain at the default value logic low.

#### P4 Rear Output Data Register

The rear output data register is used to access the individual LVCMOS output channels. This includes 32 single ended channels. Each channel is controlled by a corresponding data bit as shown in Table 41.

This rear output data register is a read/writable register. Channel operations use 32-bit, 16-bit or 8-bit data transfers. All channels of this register are fixed as output channels.

**Table 41 BAR0 Rear Output Data Register (Read/Write) - (BAR0 + 0x330008)**

Register Bit	Channel	VHDL Name	Schematic Name
0	0	RO(0)	RIO0 GCLK N
1	1	RO(1)	RIO1 N
2	2	RO(2)	RIO2 N
3	3	RO(3)	RIO3 N
4	4	RO(4)	RIO4 N
5	5	RO(5)	RIO5 N
6	6	RO(6)	RIO6 N
7	7	RO(7)	RIO7 N
8	8	RO(8)	RIO8 N
9	9	RO(9)	RIO9 N

18	18	RO(18)	RIO18 N
19	19	RO(19)	RIO19 N
20	20	RO(20)	RIO20 N
21	21	RO(21)	RIO21 N
22	22	RO(22)	RIO22 N
23	23	RO(23)	RIO23 N
24	24	RO(24)	RIO24 N
25	25	RO(25)	RIO25 N
26	26	RO(26)	RIO26 N
27	27	RO(27)	RIO27 N
28	28	RO(28)	RIO28 N
29	29	RO(29)	RIO29 N
30	30	RO(30)	RIO30 N
31	31	RO(31)	RIO31 GCLK N

Note that any registers/bits not mentioned will remain at the default value logic low.

## P16 Input Data Register

The P16 input data register is used to access the individual LVDS input channels. This includes 10 differential channels which include 2 global clock signal pairs. Each channel is controlled by a corresponding data bit as shown in Table 42.

Channel input signal levels are determined by reading this register. Channel output signals are set by writing to the P16 output data register at base address plus 0x320008.

This P16 input data register is a read only register. Channel read operations use 32-bit, 16-bit or 8-bit data transfers. All channels of this register are fixed as input channels.

**Table 42 BAR0 P16 Input Data Register (Read Only) - (BAR0 + 0x320000)**

Register Bit	Channel	VHDL Name	Schematic Name
0	0	P16 SI(0)	P16 SIO16 N
1	1	P16 SI(1)	P16 SIO14 N
2	2	P16 SI(2)	P16 SIO12 N
3	3	P16 SI(3)	P16 SIO10 N
4	4	P16 SI(4)	P16 SIO8 N
5	5	P16 SI(5)	P16 SIO6 N
6	6	P16 SI(6)	P16 SIO4 N
7	7	P16 SI(7)	P16 SIO2 N
8	8	P16 SI(8)	P16 SIO0 GCLK N
9	9	P16 SI(9)	P16 SIO18 GCLK P
10	10	P16 SI(10)	P16 SIO17 P
11	11	P16 SI(11)	P16 SIO15 P

16	16	P16 SI(16)	P16 SIO5 P
17	17	P16 SI(17)	P16 SIO3 P
18	18	P16 SI(18)	P16 SIO1 N

Note that any registers/bits not mentioned will remain at the default value logic low.

## P16 Output Data Register

The P16 output data register is used to access the individual output channels. This includes 9 differential output channels. Each channel is controlled by a corresponding data bit as shown in Table 43.

Channel output signal levels are controlled by writing this register. Channel input signals are accessed by reading the P16 input data register at base address plus 0x320000.

This P16 output data register is a write only register. Channel write operations use 32-bit, 16-bit or 8-bit data transfers. All channels of this register are fixed as output channels.

**Table 43 BAR0 P16 Output Data Register (Write Only) - (BAR0 + 0x320008)**

Register Bit	Channel	VHDL Name	Schematic Name
<b>0</b>	0	P16_SO(0)	P16_SIO18_GCLK_N
<b>1</b>	1	P16_SO(1)	P16_SIO16_P

Note that any registers/bits not mentioned will remain at the default value logic low

## 5. THEORY OF OPERATION

This section contains information regarding the design of the board. A description of the basic functionality of the circuitry used on the board is also provided. Refer to the XMC-7K/A block diagrams Figure 1 and Figure 2, as you review this material.

### PCI INTERFACE LOGIC

The PCIe bus interface logic implemented in the Acromag example design provides an 8 lane PCIe Gen 1 interface to the carrier/CPU board on XMC-7K models, 4 lanes on XMC-7A models. This interface provides access to the example design board functions.

The PCIe bus endpoint interface logic is contained within the FPGA. This logic includes support for PCIe commands, including: configuration read/write, and memory read/write. In addition, the PCIe interface supports requester and/or completion accesses. Maximum payload size of up to 1024 bytes is supported.

The logic also implements interrupt requests via message signaled interrupts. Messages are used to assert and de-assert virtual interrupt lines on the link to emulate the Legacy PCI interrupt INTA# signal.

## DDR3 Memory

A 128 Meg x 64-bit of DDR3 memory is provided for user applications. Four DDR3L memory devices are used to form a 64-bit data bus. Each of the devices are 128 Meg x 16 bit (2Gb) in size. All four devices add to 8Gb or 1GByte total memory. The DDR3 interface is implemented in FPGA banks 32, 33, and 34 (33 to 35 of Artix). DCI VRP/N resistor connections are implemented on bank 32. DCI functionality in bank 34 is achieved in the XDC by cascading DCI between adjacent banks as follows:

```
set_property DCI_CASCADE {32 34} [get_iobanks 33]
```

DCI is not required with the Artix DDR interface.

## Clock Generation

There are four FPGA clock sources available on the board.

A 2.5V LVDS 200 MHz oscillator (U22) is wired to the FPGA global clock input pins AG10 and AH10 (AB5 and AB4 of Artix). The signal names are clk200\_p and clk200\_n. This oscillator is the reference clock for the DDR3 memory interface IDELAY controller. This clock is multiplied by two to produce a 400 MHz memory clock for the DDR3 memory (Artix models only).

A 2.5V LVDS 156.25 MHz oscillator (U21) is wired to the FPGA global clock input pins AE10 and AF10 (Kintex models only). The signal names are SYS\_CLK\_clk\_p and SYS\_CLK\_clk\_n. This clock is multiplied by four to produce a 625 MHz memory clock for the DDR3 memory.

A 2.5V LVDS 156.25 MHz oscillator (U11) is wired to the FPGA MGT clock input pins C8 and C7 (AG16 and AH16 of Artix). The signal names are CLK156\_P and CLK156\_N.

A 1.8V LVCMOS 80 MHz oscillator (U13) is wired to the FPGA EMCCLK clock input at pin R24 (Y26 Artix). This oscillator provides the timing for fast parallel loading of the FPGA bitstream from flash memory on power-up.

## Multi-Gigabit Transceivers

The XMC-7 series modules provide access to up to 16 MGTs:

- Eight of the MGTs are wired to the PCIe x8 Endpoint (P15) XMC connector.
- Eight of the MGTs are wired to the (P16) XMC connector. The example design implements dual 4-lane Aurora interfaces connected to the eight transceivers.

The F Models provide access to 14 of the 16 MGTs:

- Eight of the MGTs are wired to the PCIe x8 Endpoint (P15) XMC connector.
- Four of the MGTs are wired to the (P16) XMC connector. The example design implements dual 2-lane Aurora interfaces.

- Two of the MGTs are wired to SFP+ ports. The example design implements a 1000-BaseX Ethernet interface on each SFP+ port.

### 32MB Linear BPI Flash

A Linear BPI FLASH memory provides 64 megabytes of non-volatile storage that is used for FPGA configuration and MicroBlaze program code or data storage. The FLASH device is Micron part number PC28F512G18F. The lower 16 megabytes of memory space are dedicated to storage of the FPGA bitstream (32 megabytes on XMC-7A models). The remaining 48 megabytes are available for MicroBlaze program and data storage (32 megabytes on XMC-7A models).

The Xilinx LogiCORE IP AXI EMC v3.0 provides the interface between the internal AXI bus and the Micron FLASH device.

### JTAG Port

The JTAG port can be used to program the FPGA and access the device for hardware and software debug. The JTAG signals are routed to both the XMC P15 connector and either the AXM (P1) connector on AXM models or the VHDCI (P1) on the Front I/O models.

The JTAG port also allows a host computer to download a bitstream to the FPGA or Flash using the Xilinx Vivado software tool. In addition, the JTAG port allows debug tools such as the ChipScope™ Pro Analyzer tool or a software debugger to access the FPGA.

### Encryption Key Storage

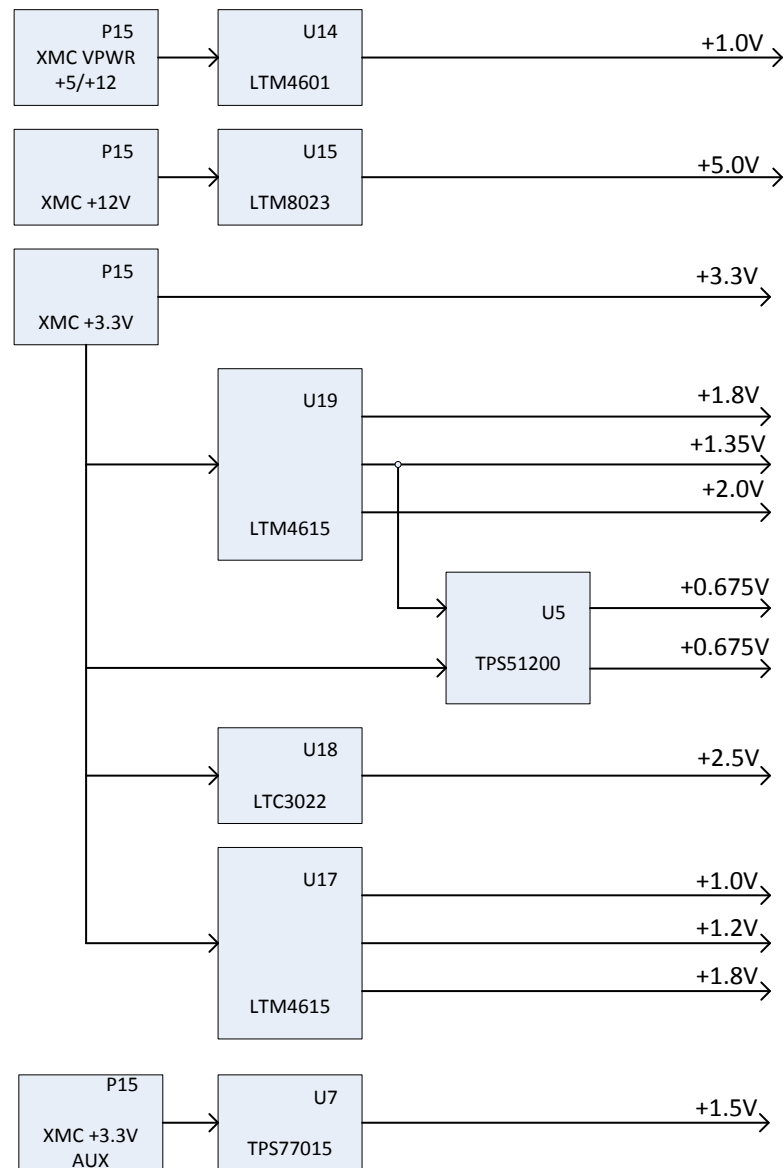

In all 7 series FPGA devices, the FPGA bitstream which contains sensitive customer IP, can be protected with 256-bit AES encryption and HMAC/SHA-256 authentication to prevent unauthorized copying of the design. The FPGA performs decryption on the fly during configuration using an internally stored 256-bit key. This key can reside in volatile RAM or in nonvolatile eFUSE bits. The volatile RAM is powered from the 3.3V\_AUX pin of the XMC P15 connector.

### Power System Devices

The power for the XMC-7 series modules is taken from the XMC P15 connector VPWR\_5/12, 12 Volt, and the 3.3 Volt power pins. Table 44 and Figure 4 show the source and capacity of each of the power regulators on the board.

**Table 44 Power Distribution**

Device	Reference Designator	Description	Power Rail Volts	Power Rail Current
LTM4601	U14	FPGA VCCINT	+1.0	12.0 A
LTM8023	U15	AXM module power	+5.0	2.0 A
LTM4615	U19	FPGA VCCO, FLASH	+1.8	4.0 A
LTM4615	U19	FPGA VCCO,DDR3	+1.35	4.0 A
LTM4615	U19	FPGA VCC AUX	+2.0	1.5 A
TPS51200	U5	DDR3 VREF	+0.675V	+/-3 A
TPS51200	U5	DDR3 Termination	+0.675V	+/-3 A
LTC3022	U18	FPGA VCCO	+2.5	1.5 A
LTM4615	U17	FPGA MGTAVCC	+1.0	4.0 A
LTM4615	U17	FPGA MGTAVTT	+1.2	4.0 A
LTM4615	U17	FPGA MGTVCCAUX	+1.8	1.5 A
TPS77015	U13	FPGA BBRAM	+1.5V	0.05 A

**Figure 4 Power Distribution**

## System Monitor

The System Monitor provides status information for the 7 series device. The system monitor is located in the center of the FPGA die. The System Monitor function is built around dual 12-bit, 1-megasamples per second Analog-to-Digital Converter. The system monitor is used to measure FPGA physical operating parameters such as on-chip power supply voltages and die temperature.

## 6. FPGA FIRMWARE EXAMPLE DESIGN

---

Acromag provides an FPGA firmware example design that provides host access to each of the hardware peripherals on the XMC module. The example design is intended to be a starting point from which customers will develop their customized applications. The example design is implemented using the Xilinx Vivado development environment "Project Mode" design flow.

### **XMC-7A200/CC and XMC-7KxxxAX Models Block Diagram Overview**

The hierarchy of the AXM Model example design is shown in Figure 5 below. Figure 5 is a screen clipping from the "Hierarchy" tab of the "Sources" pane in the Vivado development environment. The example design consists of a combination of VHDL source files and a Xilinx Vivado IP Integrator block diagram. At the highest level of the hierarchy is the `system_top` VHDL source file, shown in the figure with the least levels of indentation. This top-level module instantiates the following three lower level modules: `AXM_Dxx`, `system`, and `aurora_8b_10b_0_exdes`. "`AXM_Dxx`" is the top of the hierarchy used to instantiate any of Acromag's digital AXM modules. "`System`" is the Vivado IP Integrator block diagram source where the majority of the example design logic is located. "`aurora_8b_10b_0_exdes`" is the wrapper for the Xilinx IP Core Generator generated example design for Aurora.

The IP Integrator block diagram labeled "`system`" is compiled to produce a lower level hierarchy of VHDL source files that are shown beneath "`system`". The "+" symbol to the left of each of the labeled subsystems indicates that additional source files exist at lower levels in the hierarchy that are not shown.

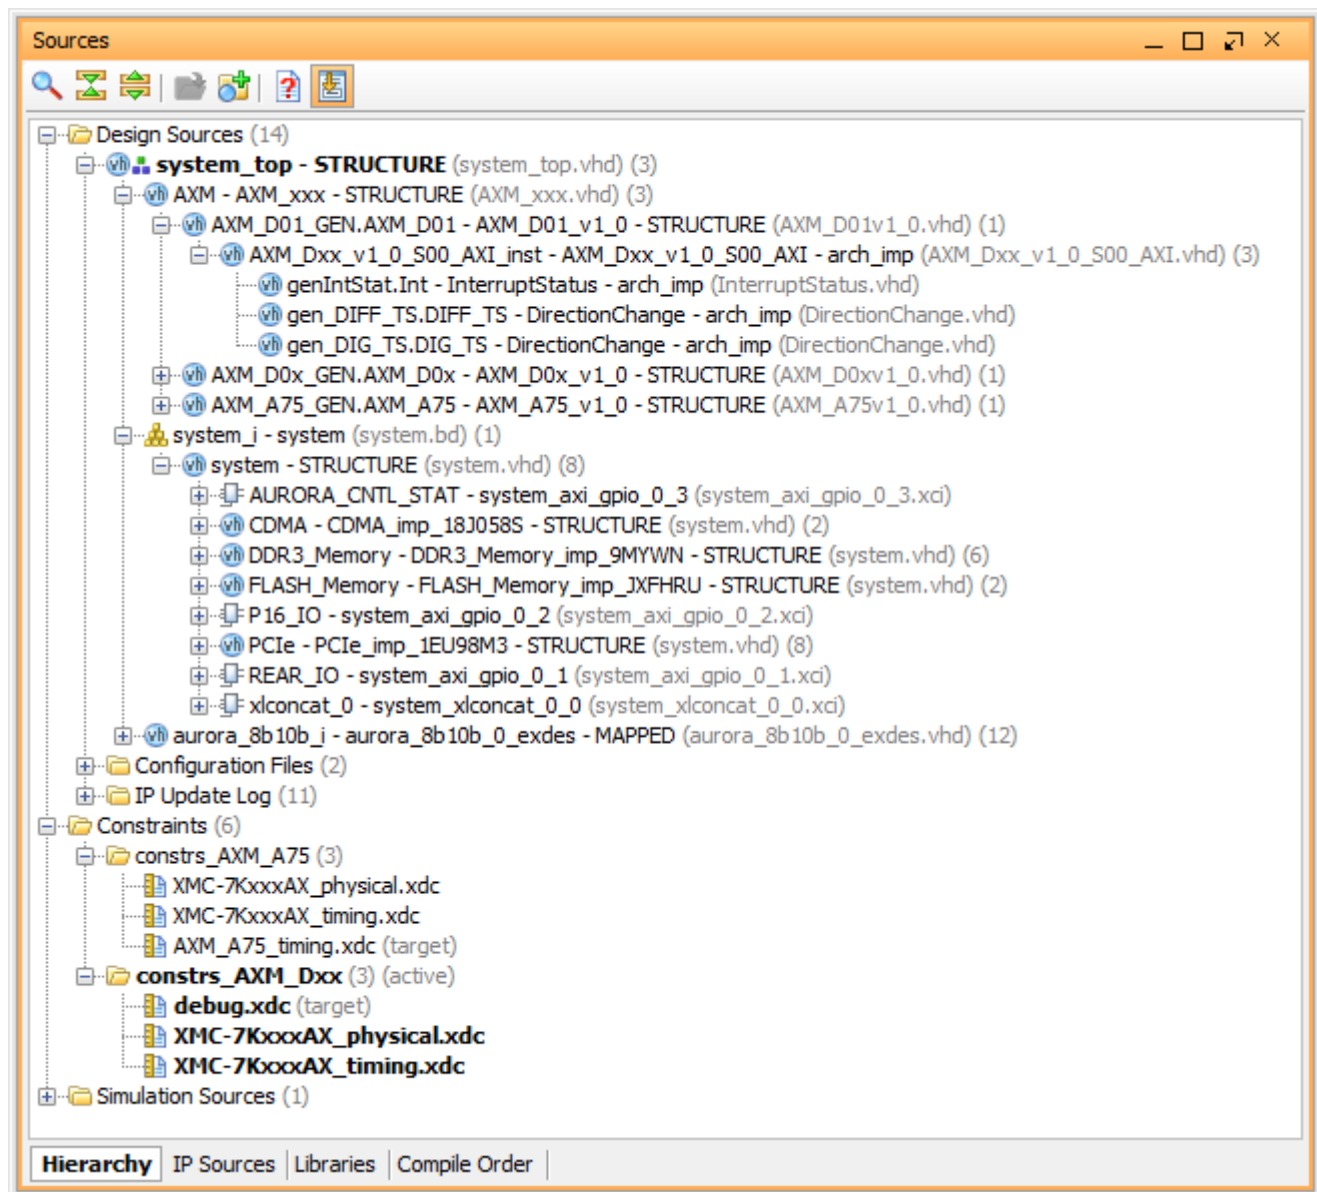

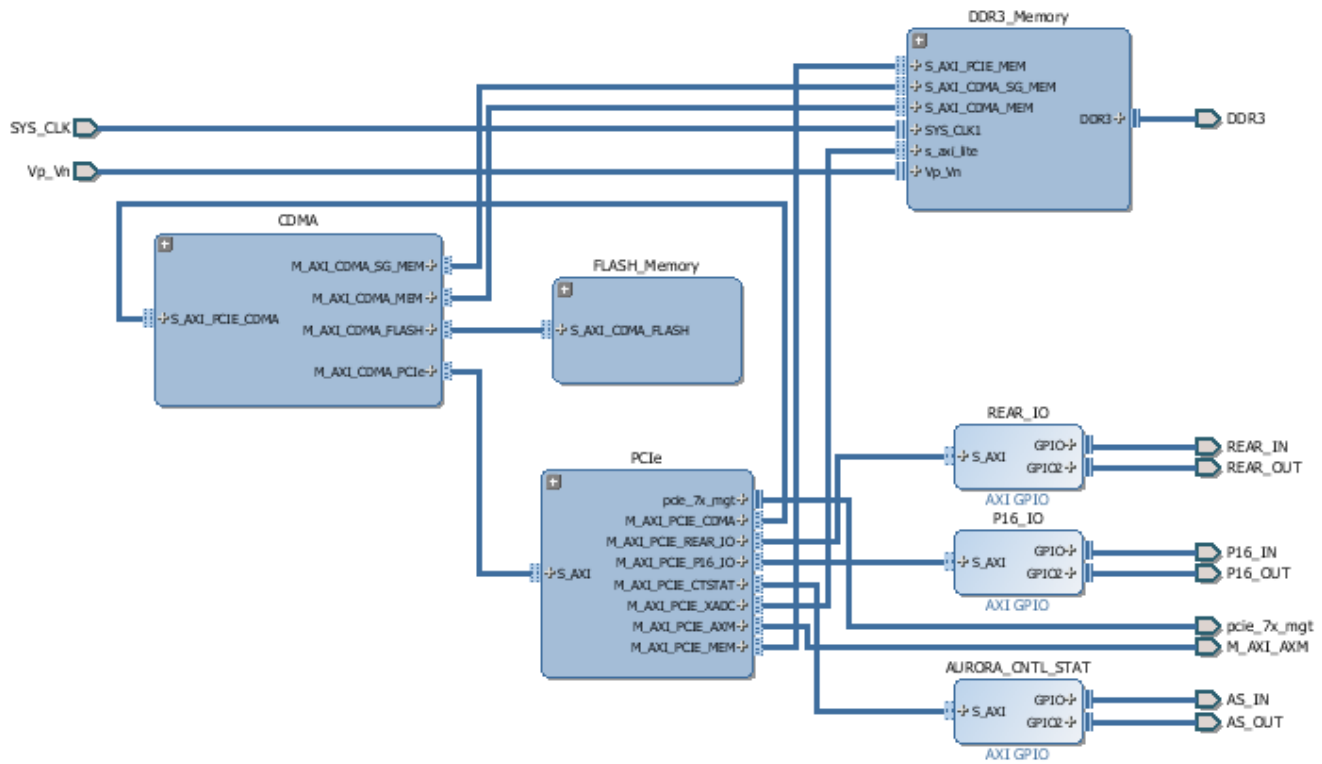

Figure 5 Design Sources Hierarchy

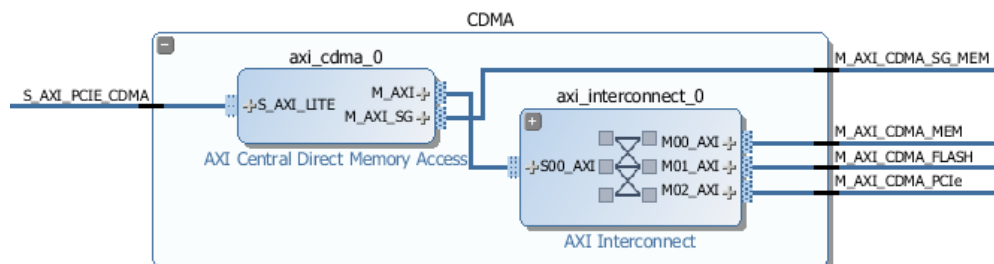

The top level block diagram of the example design is shown in Figure 6 below. This view has reduced detail, showing only the AXI interfaces between blocks and interfaces to external I/Os. (For more detail on AXI bus see [UG761](#)). Blocks with a dark background color include lower level blocks which are expanded and shown in the following paragraphs. The PCIe interface provides the path through which the host processor communicates with the XMC module peripherals. This diagram shows that the host processor can directly access DDR3

memory, REAR\_IO, P16\_IO, AURORA\_CNTL\_STAT and CDMA registers. The host processor cannot directly access FLASH memory, this must be done using the CDMA.

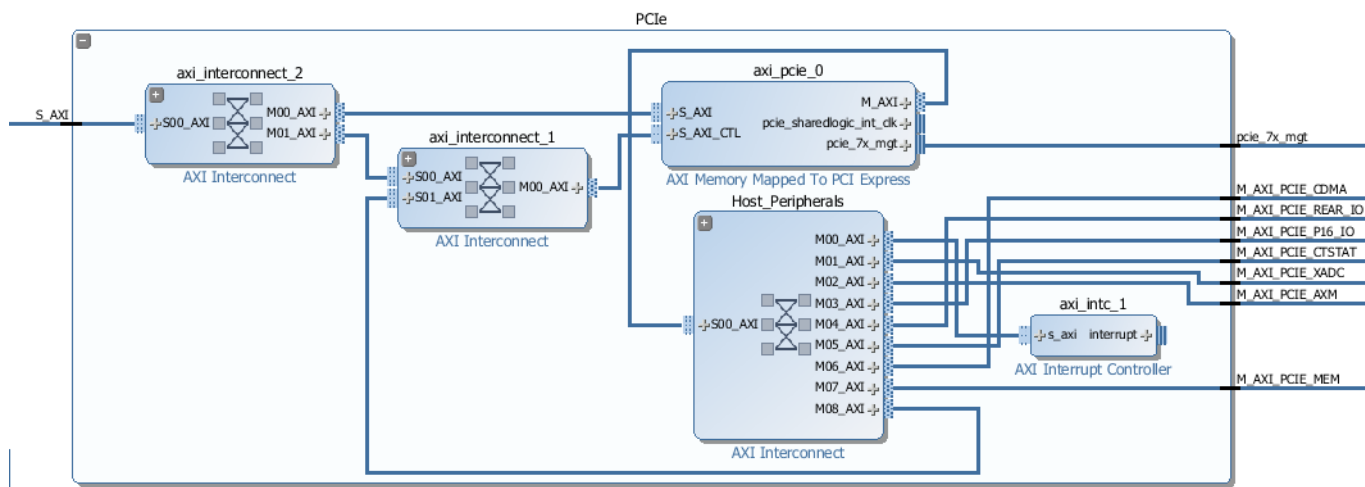

**Figure 6 Block Diagram Top Level**

The hierarchical block named “CDMA” (Central Direct Memory Access) shown in Figure 7 includes two sub blocks: axi\_cdma\_0 and axi\_interconnect\_0. The AXI interconnect expands the M\_AXI interface to allow it to transfer data to and from the three slave devices: DDR3 memory, Flash memory, and the PCIe bridge control registers. The CDMA controller is configured to support scatter gather. The scatter gather master interface can only access DDR3 memory.

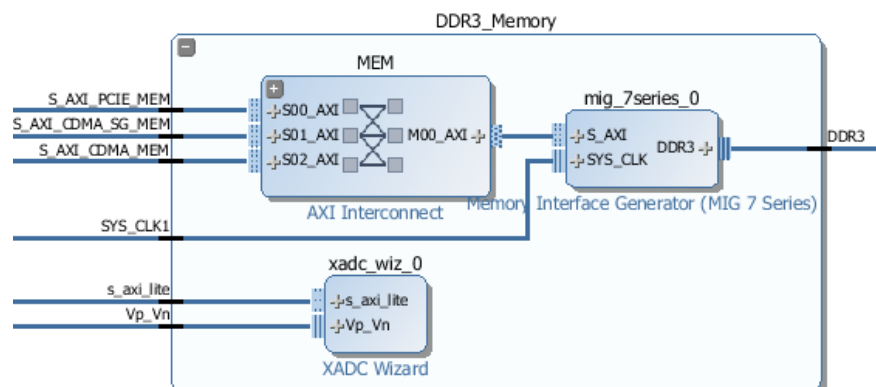

**Figure 7 Block Diagram CDMA**

The hierarchical block named “PCIe” (PCI Express) shown in Figure 8 includes the axi\_pcie, axi\_intc, and three interconnect blocks. The AXI slave interface entering the block from the left comes from the CDMA controller. Axi\_interconnect\_2 expands the CDMA master interface to two master interfaces to allow the CDMA controller to transfer data to and from both the PCIe control registers in the PCIe interface and host memory through the PCIe bridge. Axi\_interconnect\_1 expands the axi\_pcie S\_AXI\_CTL slave interface to two slave interfaces to allow reads/writes from both the CDMA controller and the axi\_pcie master. The latter allows the host processor to read/write BARs (Base Address Registers) within the PCIe bridge in order to support non-contiguous host memory buffers. The axi\_interconnect block named “Host Peripherals” expands the PCIe master interface to provide access to the nine devices shown. Axi\_intc\_1 is an interrupt controller whose output drives the interrupt input to the PCIe controller. This connection is not shown due to the reduced detail view used to produce this diagram.

**Figure 8 Block Diagram PCIe**

The hierarchical block named “DDR3\_Memory” shown in Figure 9 includes an axi\_interconnect, XADC A/D converter (System Monitor), and the DDR memory interface mig\_7series\_0. The axi\_interconnect expands the slave interface port of the memory interface to three ports. The three masters that can access DDR3 memory are the PCIe bridge, and the two master ports of the CDMA controller: scatter gather and data transfer. The axi\_interconnect provides many bus interface functions including arbitration, width conversion, buffering, up-sizing, down-sizing and synchronizing. The XADC block was included in the DDR3\_Memory block because it provides die temperature monitor outputs used by the memory interface to adjust its timing to compensate for temperature dependent timing.

**Figure 9 Block Diagram DDR3 Memory**

Figure 10 shows the expanded view of the MEM AXI interconnect block of Figure 9. Performance tuning can be accomplished by configuring the AXI Crossbar block. Double-clicking on the xbar block invokes the Re-customize IP option in Vivado. The Re-customize IP dialog is shown in the following paragraph.

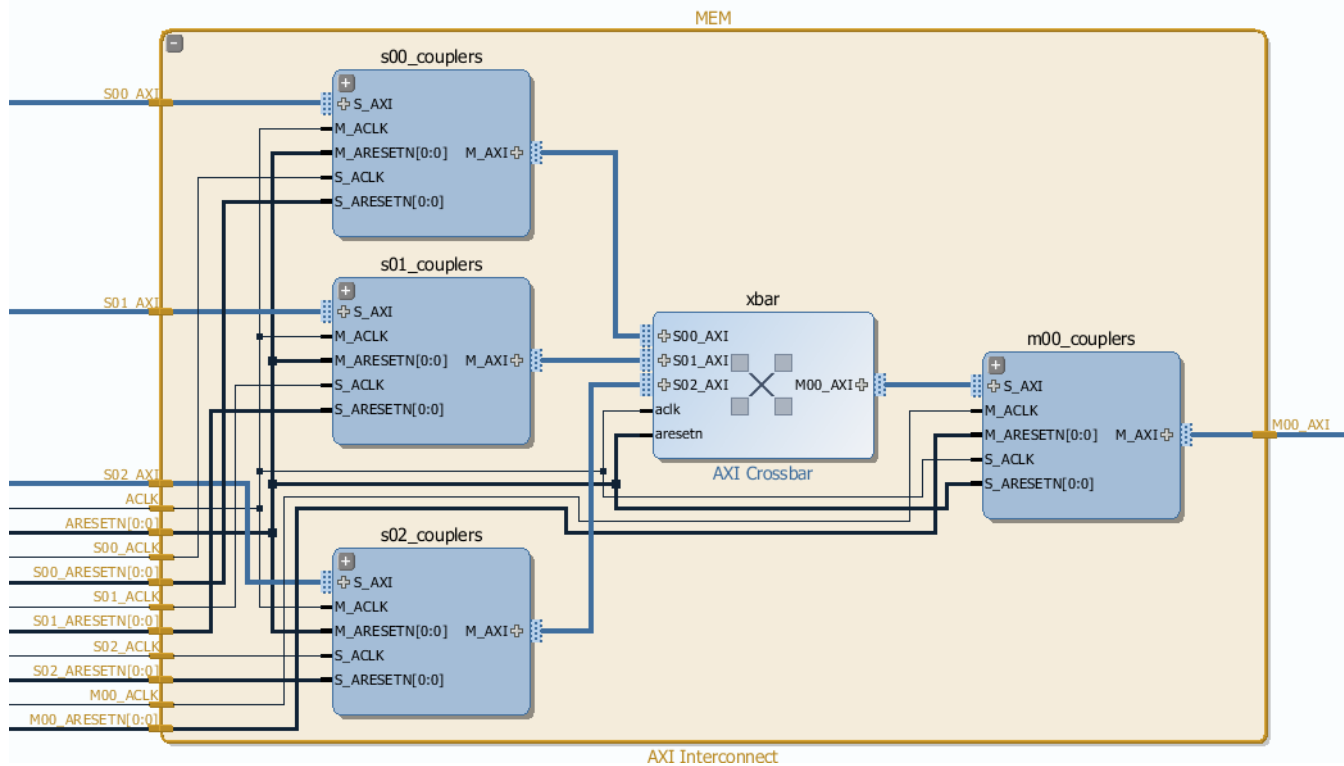

Figure 10 MEM AXI Interconnect

The Slave Interfaces tab of the AXI Crossbar Re-customize dialog box provides the option to choose the arbitration scheme and assign priorities to each of the slave interfaces. Other performance tuning options are also available. See the Xilinx LogiCORE IP AXI Interconnect Product Guide [PG059](#) for a detailed description.

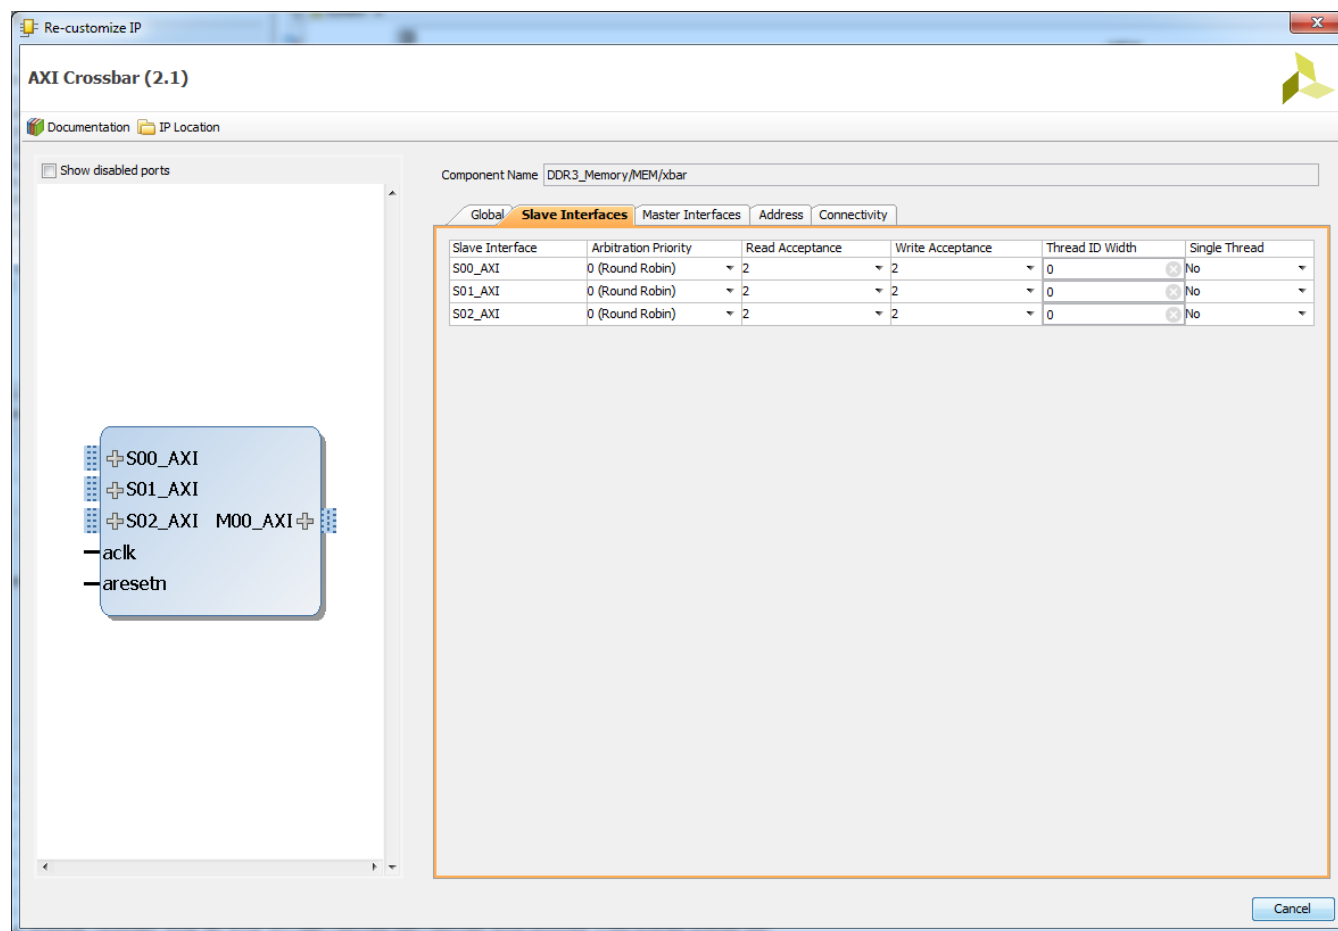

Figure 11 AXI Crossbar Slave Interface Settings

Table 45 shows a screen clipping from the Address Editor tab of the Block Design view. The offset address and block size for each peripheral can be set using this editor. This table shows the master interfaces of each peripheral and lists the devices that each can access along with the base addresses.

Cell	Slave Interface	Base Name	Offset Address	Range	High Address
CDMA/axi_cdma_0					
Data (32 address bits : 4G)

**Table 45 XMC-7KxxxAX Address Map**

## XMC-7KxxxF Models Block Diagram

The hierarchy of the F Model example design is shown in Figure 12 below. Figure 12 is a screen clipping from the “Hierarchy” tab of the “Sources” pane in the Vivado development environment. The example design consists of a combination of VHDL source files and a Xilinx Vivado IP Integrator block diagram. At the highest level of the hierarchy is the system\_top VHDL source file, shown in the figure with the least levels of indentation. This top-level module instantiates the following three lower level modules: AXM\_Dxx, system, and aurora\_8b\_10b\_0\_exdes. “AXM\_Dxx” is the top of the hierarchy used to instantiate any of Acromag’s digital AXM modules. “System” is the Vivado IP Integrator block diagram source where the majority of the example design logic is located. “aurora\_8b\_10b\_0\_exdes” is the wrapper for the Xilinx IP Core Generator generated example design for Aurora.

The IP Integrator block diagram labeled “system” is compiled to produce a lower level hierarchy of VHDL source files that are shown beneath “system”. The “+” symbol to the left of each of the labeled subsystems indicates that additional source files exist at lower levels in the hierarchy that are not shown.

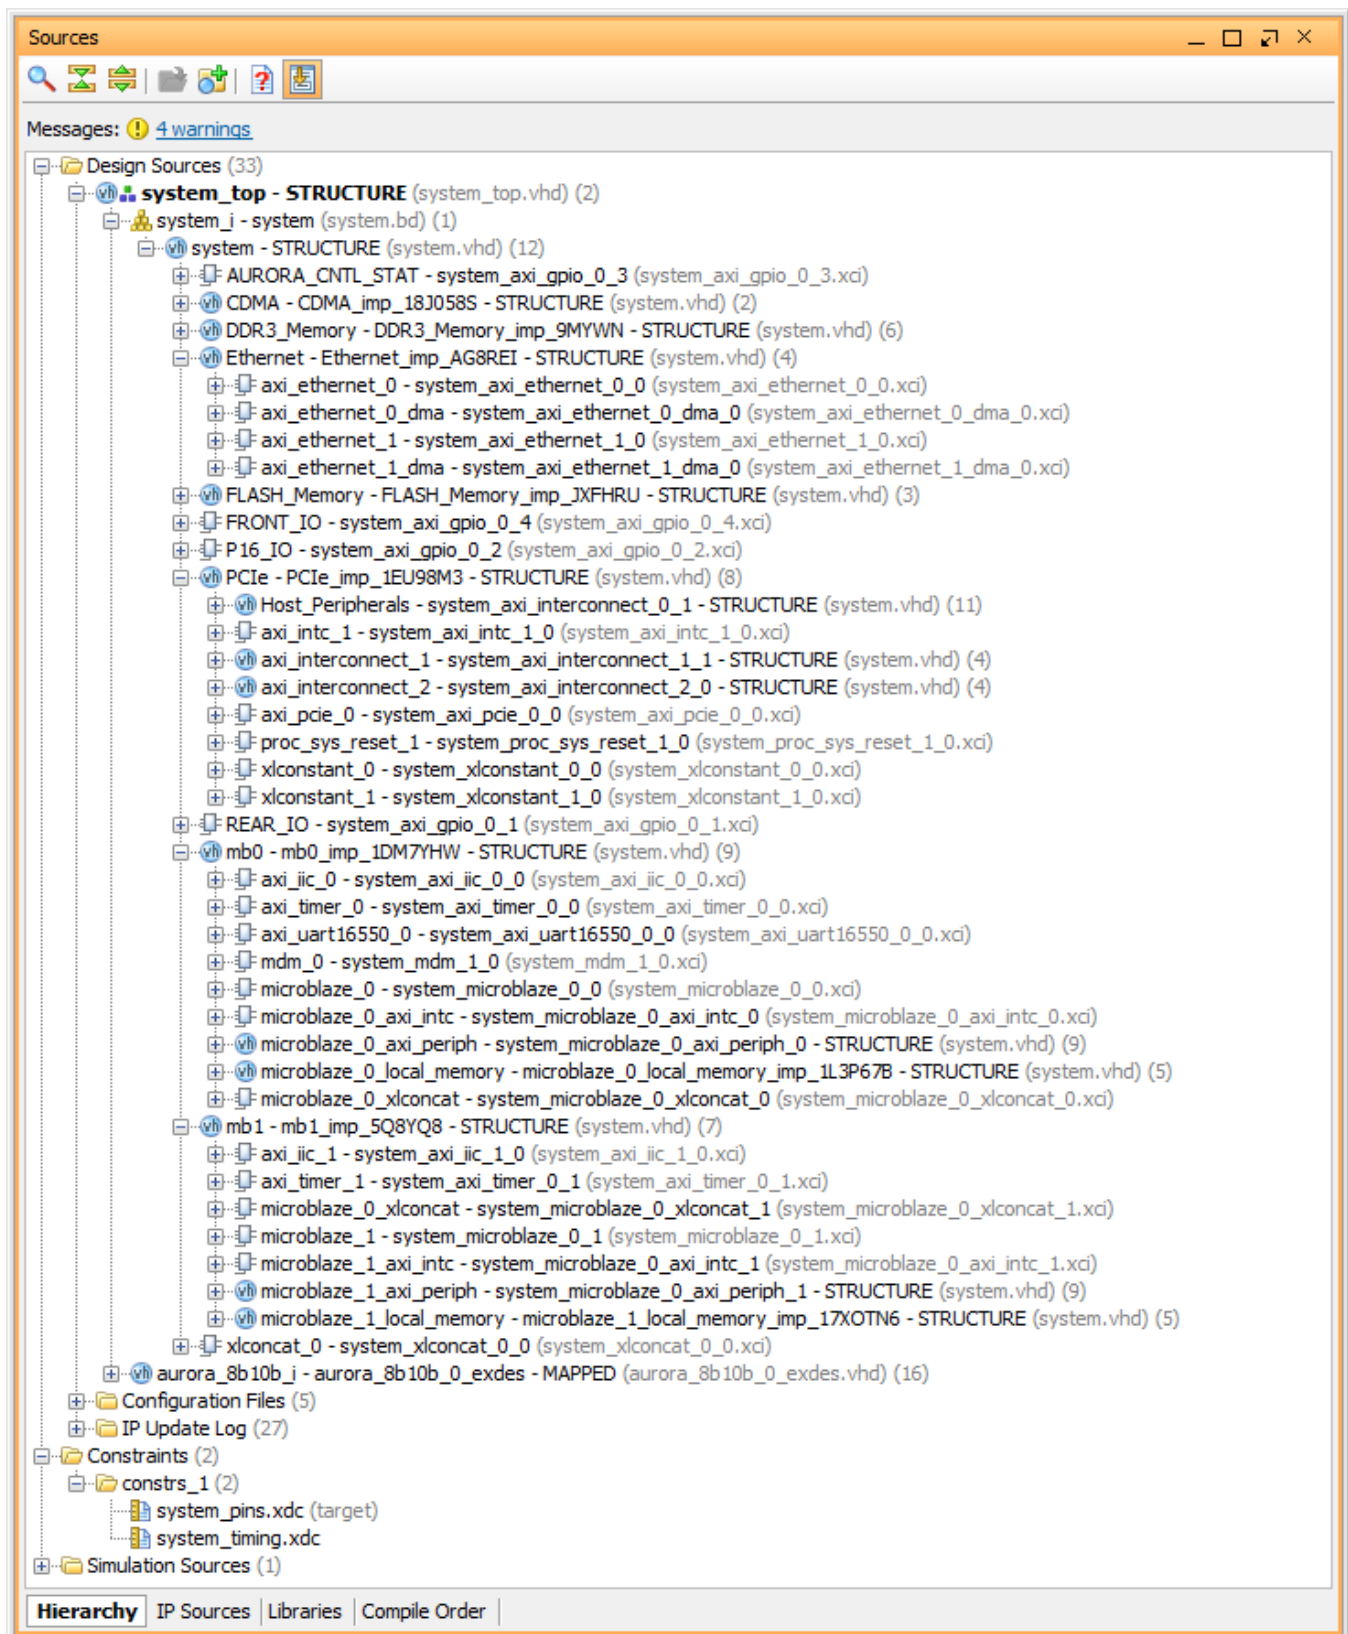

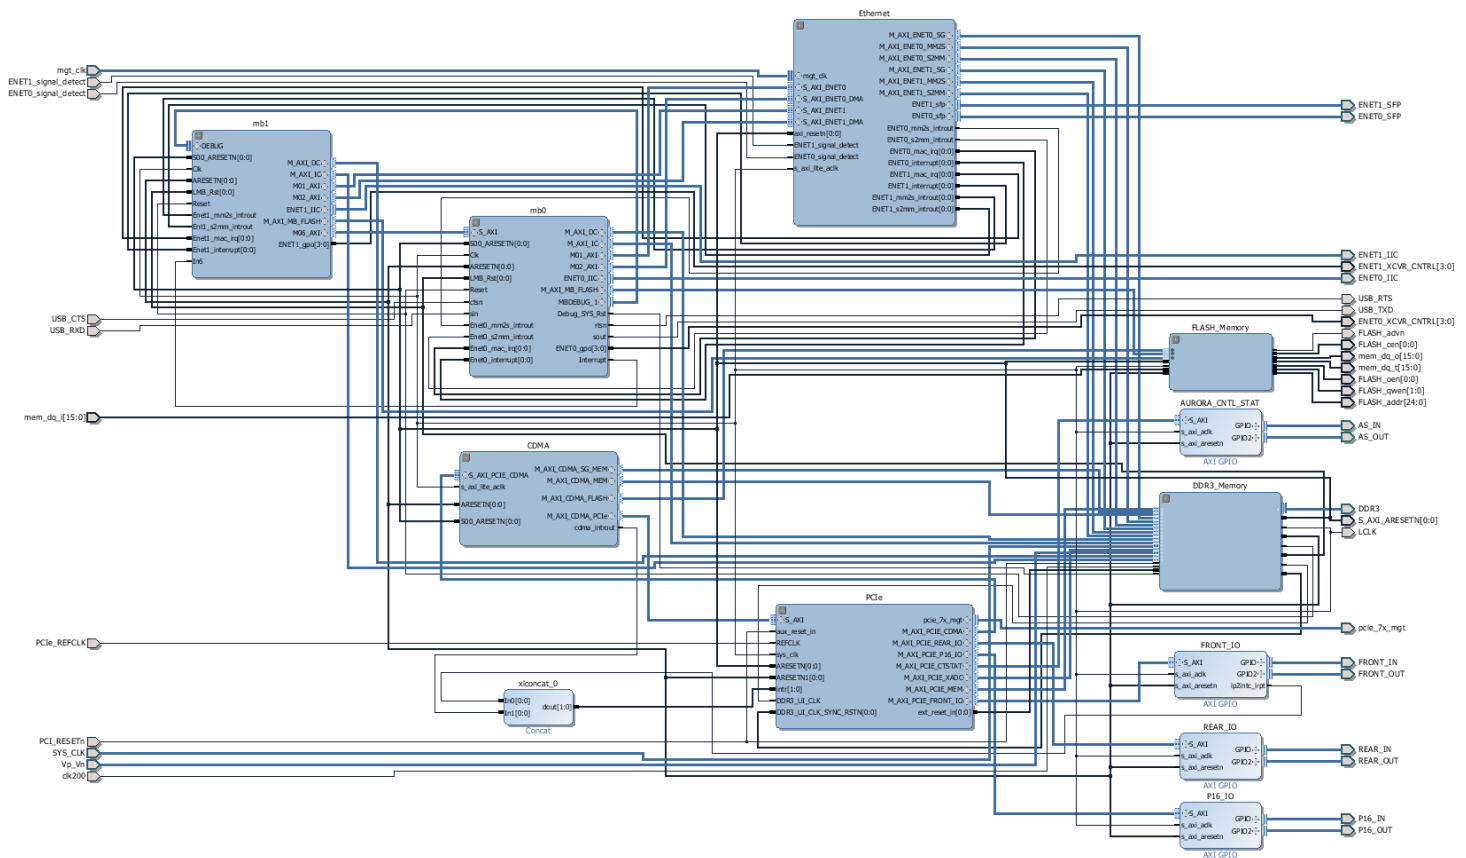

Figure 12 Design Sources Hierarchy

### Figure 15 Block Diagram Ethernet Subsystem

### Figure 16 Block Diagram Microblaze 0

### Figure 17 Block Diagram Microblaze 1

## 7. XMC-7KxxxF Software

The XMC-7KxxxF models include two MicroBlaze processors that manage the TCP/IP stacks in the example design. This section describes the embedded system software. There are two Ethernet ports on the board. Each port has an associated DMA controller and MicroBlaze processor. The Vivado project folder contains an SDK project subfolder for the embedded system named XMC-7KxxxF.sdk. There are four projects in the workspace, two for each MicroBlaze processor. The projects named srec\_bootloader\_0 and srec\_bootloader\_1 are small programs that are included in the FPGA configuration bitstream and are loaded into block RAMs during FPGA configuration. The purpose of the srec\_bootloader is to copy the larger program, EchoServer, from flash memory to DDR3 SDRAM and start execution of the EchoServer program. The EchoServer is a simple program that will echo ICMP packets received from a "PING" request. The EchoServer0 program manages the SFP1 Ethernet port. It reports status messages over the USB/UART in the front panel field I/O connector. The UART configuration is 9600 baud, 8 data bits, 1 stop bit, no parity. It will respond to IP address 192.168.1.10 on subnet 255.255.255.128. The Echoserver1 program manages the SFP2 Ethernet port at IP address 192.168.1.138 on subnet 255.255.255.128. It reports status messages over the JTAG UART when a Xilinx Platform USB Cable is connected to the JTAG connector.

### Bootloader Memory Map

Each of the MicroBlaze processors has separate areas assigned in flash and DDR3 SDRAM address space as follows:

srec\_bootloader\_0

FLASH\_IMAGE\_BASEADDR 0x61000000 size 0x010000

DDR3\_SDRAM\_S\_AXI\_BASEADDR 0x80000000 size 0x20000000

srec\_bootloader\_1

FLASH\_IMAGE\_BASEADDR 0x62000000 size 0x01000000

DDR3\_SDRAM\_S\_AXI\_BASEADDR 0xA0000000 size 0x20000000

### EchoServer Memory Map

When running the echoserver application, three separate DDR3 SDRAM memory areas are assigned to prevent each device from overwriting another device's data.

echoserver\_0

DDR3\_SDRAM\_S\_AXI\_BASEADDR 0x81000000 size 0x1F000000

echoserver\_1

DDR3\_SDRAM\_S\_AXI\_BASEADDR 0xA0000000 size 0x20000000

DMA Buffer (PCIe BAR1 memory space)

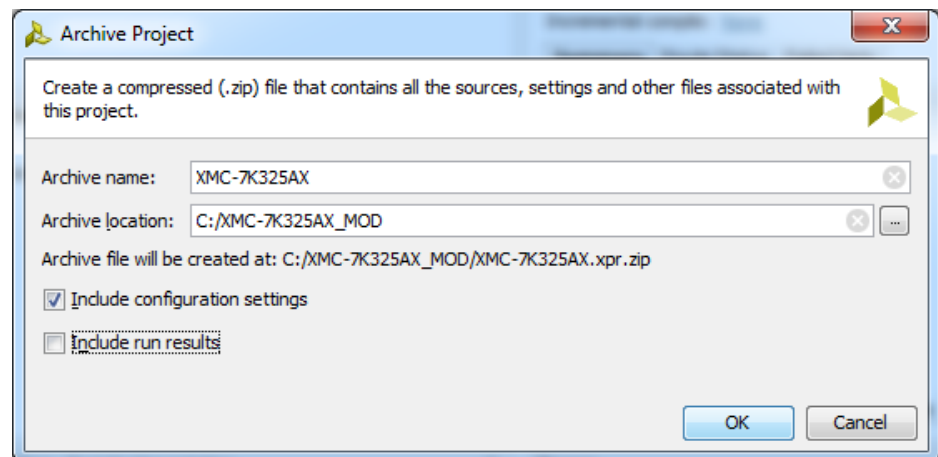

DDR3\_SDRAM\_S\_AXI\_BASEADDR 0x80000000 size 0x01000000

## 8. DESIGN MODIFICATION WALK THROUGH

This section details the steps required to make a simple modification to the example design and compile the project files to produce a new FPGA configuration file. The process to update the configuration flash with the new file will also be covered. The example design has the REAR\_IO interface configured as two unidirectional 32-bit single-ended ports, one input and one output. In this walk through we will reconfigure the REAR\_IO to be a 32-bit bidirectional differential port. This change will require updating the block diagram, top level VHDL source, and the constraints file.

### Copy the Project

To begin we will copy the example design project to a new work area. Create a new folder “C:\XMC-7K325AX\_MOD”. Open the example project C:\XMC-7K325AX.xpr. Under the File menu, select the “Archive Project” command. Enter “C:\XMC-7K325AX\_MOD” in the Archive location field as shown in Figure 18. Select “Include configuration settings”. Deselect “Include run results”. Hit OK.

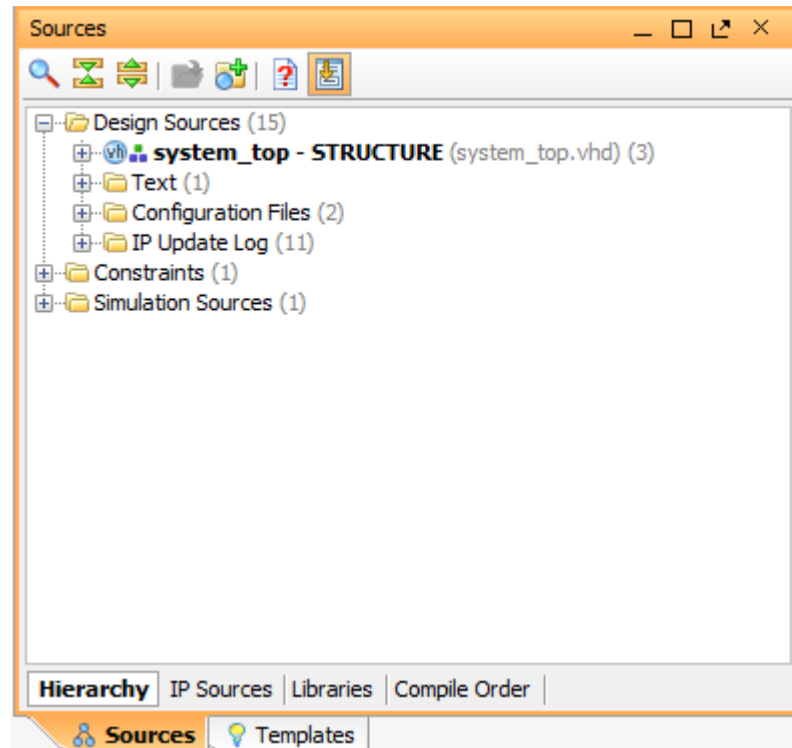

**Figure 18 Archive Project Dialog**

Navigate to the “C:\XMC-7K325AX\_MOD” folder and extract the archived project files. Open the Vivado project “XMC-7K325AX.xpr” in the XMC-7K325\_AX folder.

## Modify the Source Files

The “Sources” pane will display the “Hierarchy” tab as shown below in Figure 19. Click the “+” symbol left of “system\_top – STRUCTURE” to expand the hierarchy.

**Figure 19 Vivado Sources Pane**

Beneath “system\_top” are the three components instantiated in system\_top.vhd: AXM\_Dxx.vhd, system.bd, and aurora\_8b10b\_exdes.vhd. AXM\_Dxx.vhd is a top level wrapper that instantiates the selected Acromag AXM module source. This selection is made by passing the appropriate value for the VHDL generic AXM\_MODULE to system\_top. This is configured by choosing the appropriate Design run which will be explained in a later section. Next open the Vivado IP Integrator block design by double-clicking on the line “system\_i – system (system.bd)(1)”.

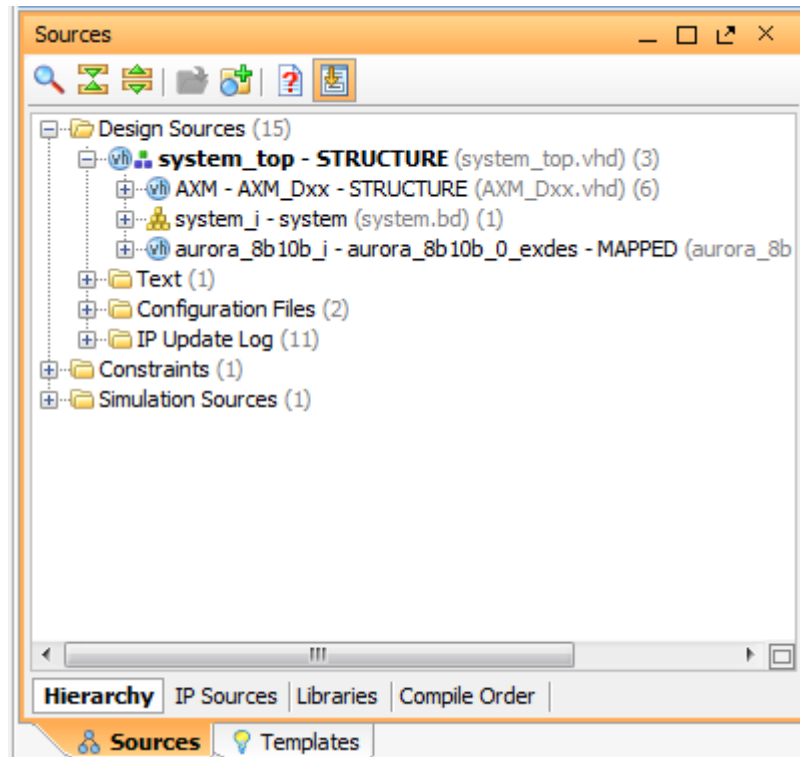

Figure 20 Sources Pane showing expanded hierarchy

The block diagram will open as shown in Figure 21. Double-click on the REAR\_IO block located in the lower right portion of the diagram.

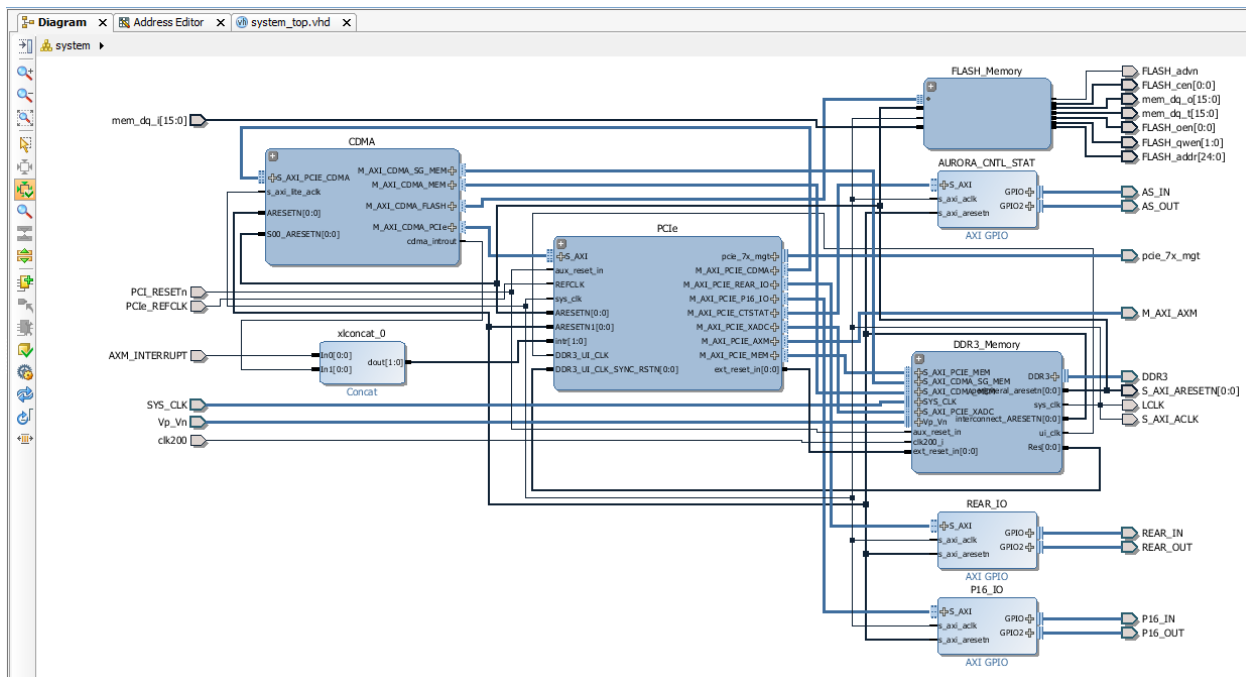

Figure 21 Block Diagram

The Re-customize IP dialog for the AXI\_GPIO IP will appear as shown in Figure 22.

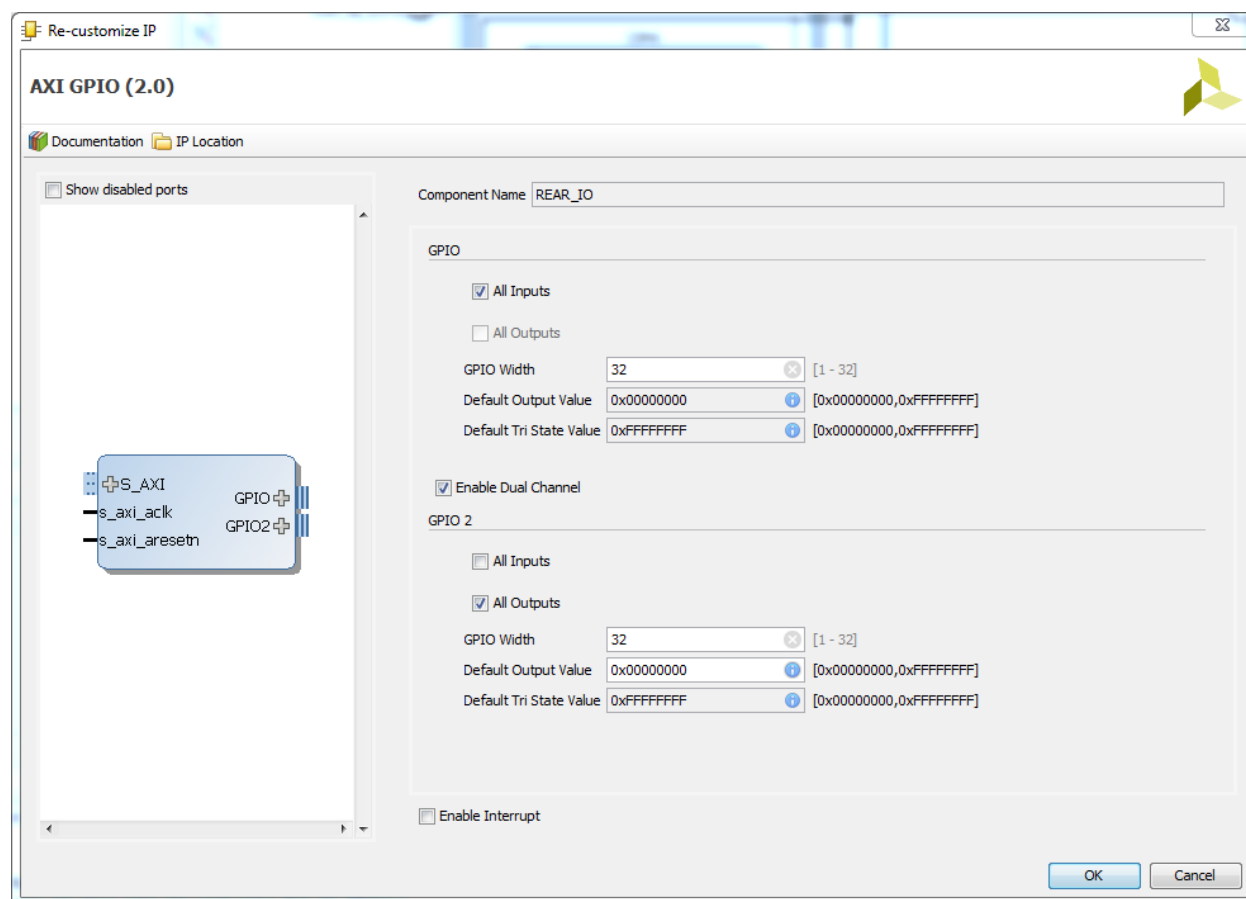

Figure 22 Re-customize AXI GPIO

De-select the “All Inputs” check box. De-select “Enable Dual Channel”. Hit OK. The dialog box should look like Figure 23.

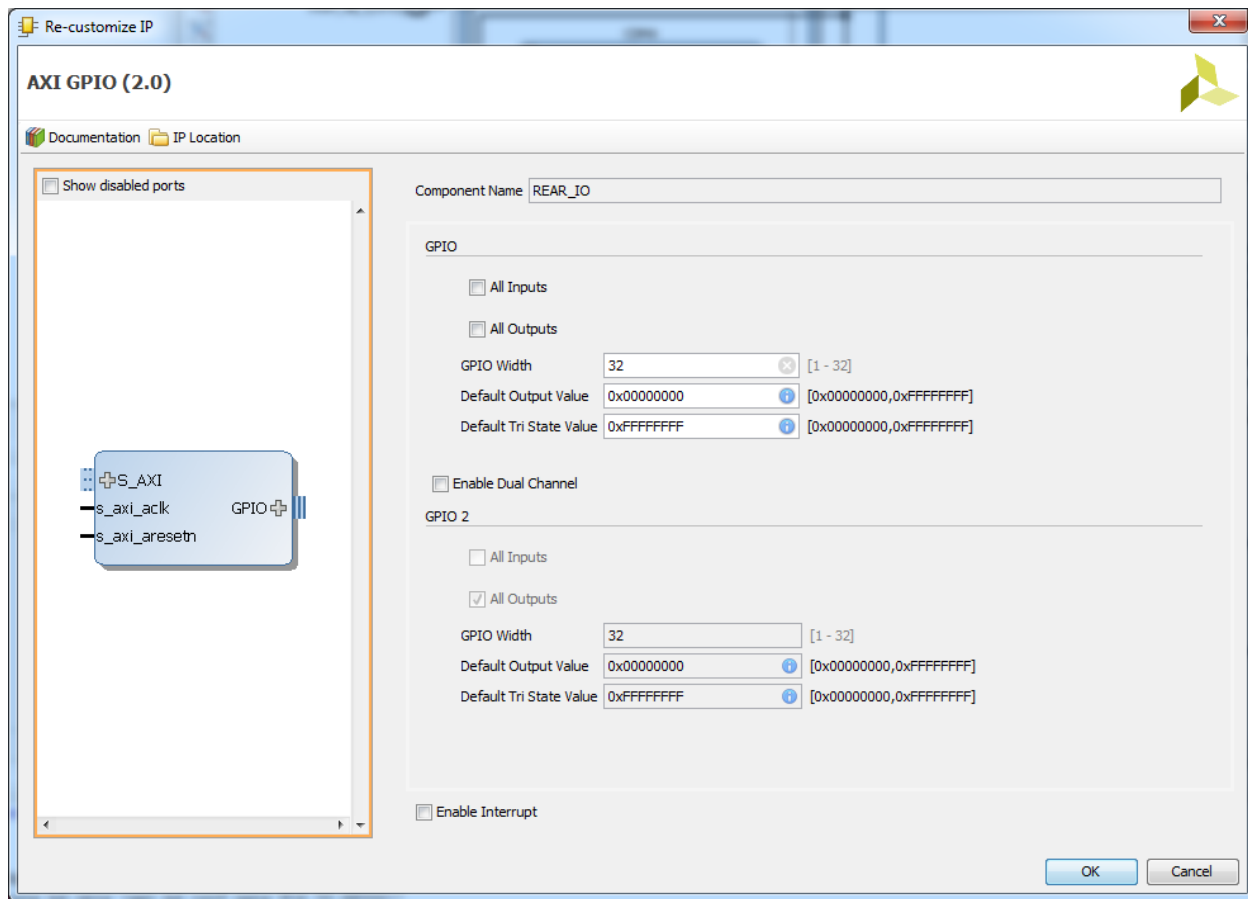

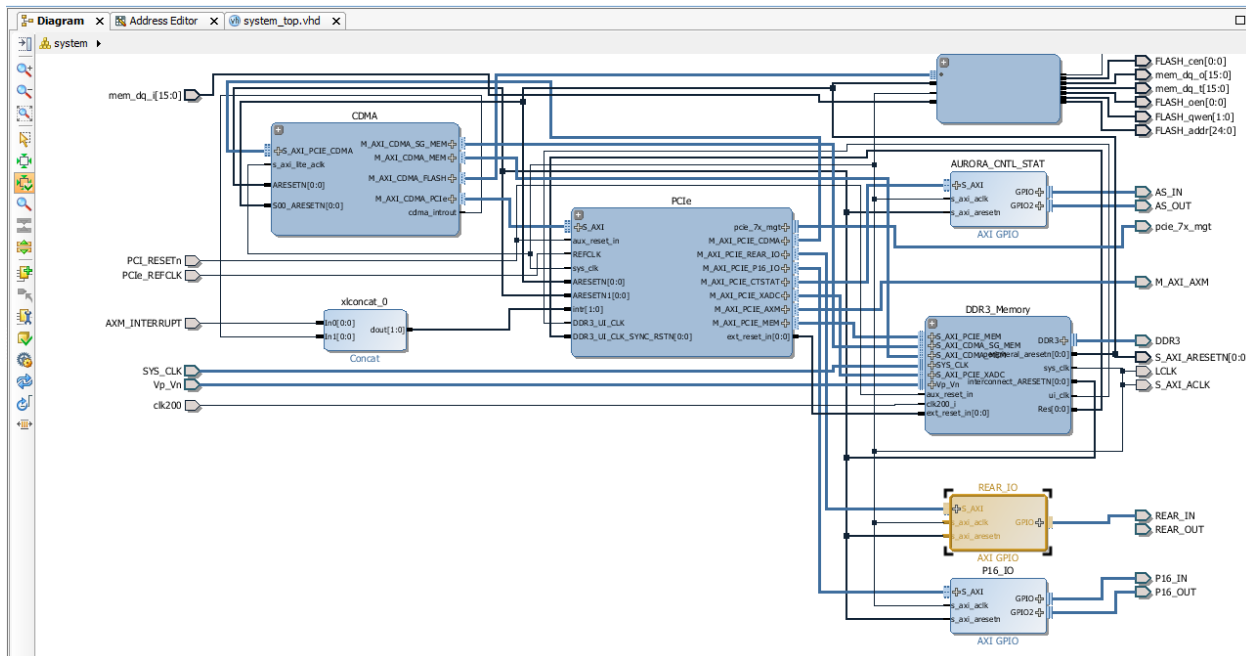

Figure 23 Re-configured REAR\_IO

The block diagram has changed as shown in Figure 24. There is now only one GPIO port on the REAR\_IO block.

**Figure 24 Modified Block Diagram**

Delete the port labeled “REAR\_OUT” by right-clicking on the port and selecting the “delete” operation. Next, left-click on the port labeled “REAR\_IN”. The “External Interface Properties” pane will now focus on the “REAR\_IO\_GPIO” port as shown in Figure 25.

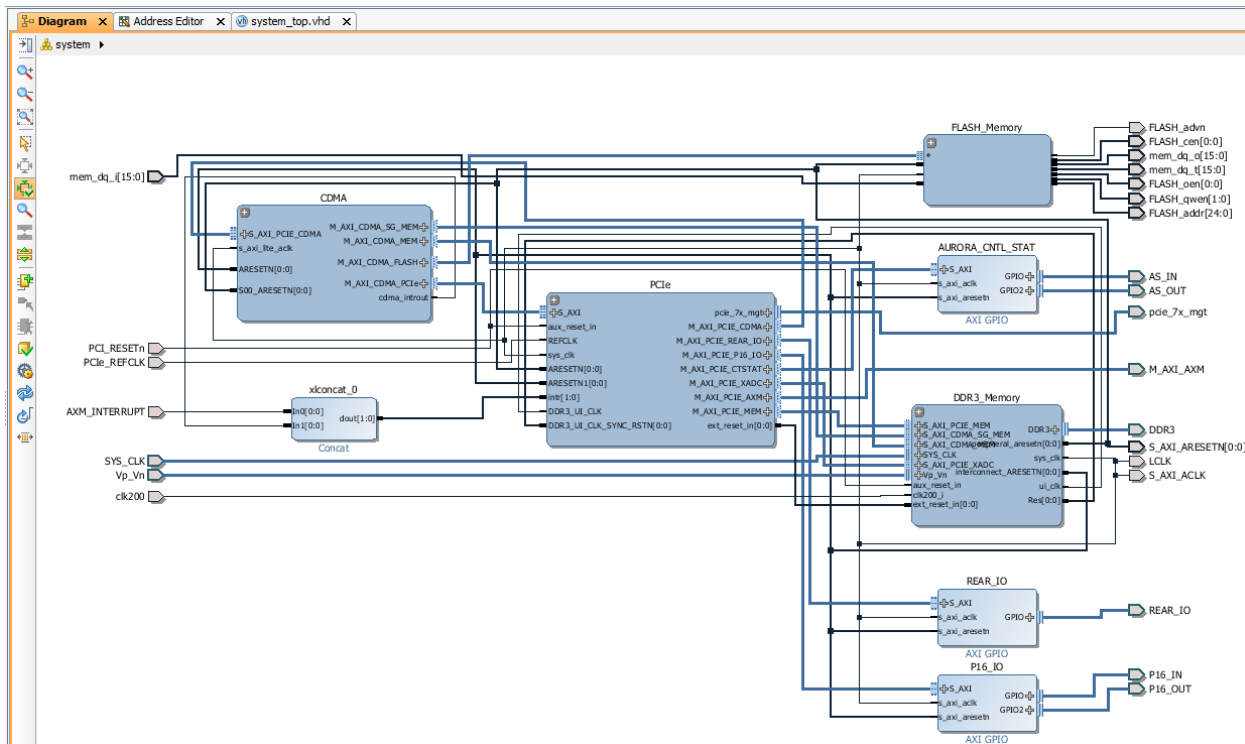

**Figure 25 External Interface Properties pane**

Change the name from “REAR\_IN” to “REAR\_IO” as shown in Figure 26.

**Figure 26 External Interface Properties modified**

The block diagram should now look like Figure 27 with a single GPIO port named REAR\_IO on the REAR\_IO block.

**Figure 27 Block Diagram modified**

Save the modifications to the block diagram by typing Ctrl-S or selecting “Save Block Design” from the “File” menu. Next click on the “Generate Block

Design” command under “IP Integrator” in the “Flow Navigator” pane to generate the underlying VHDL files for the block design as shown in Figure 28.

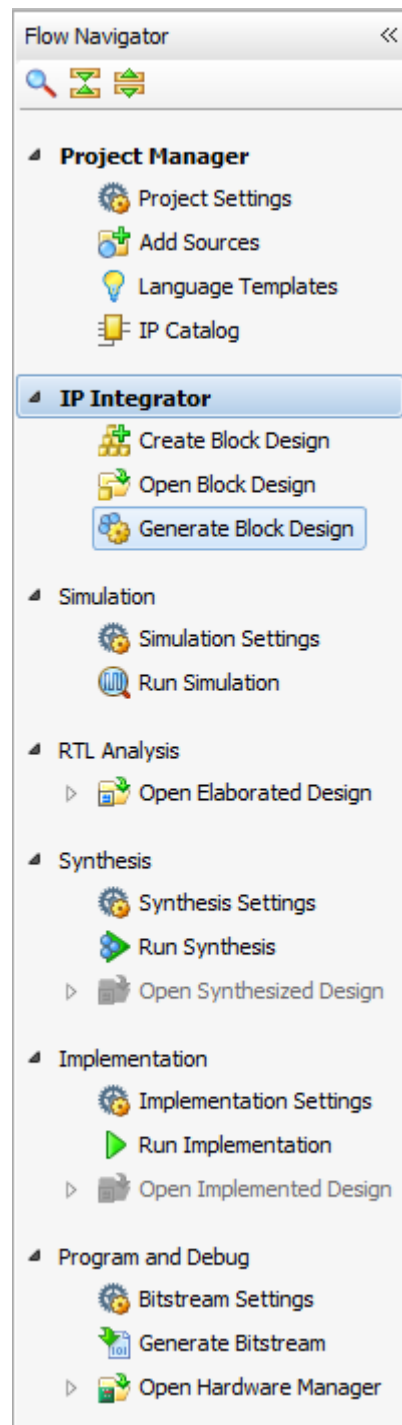

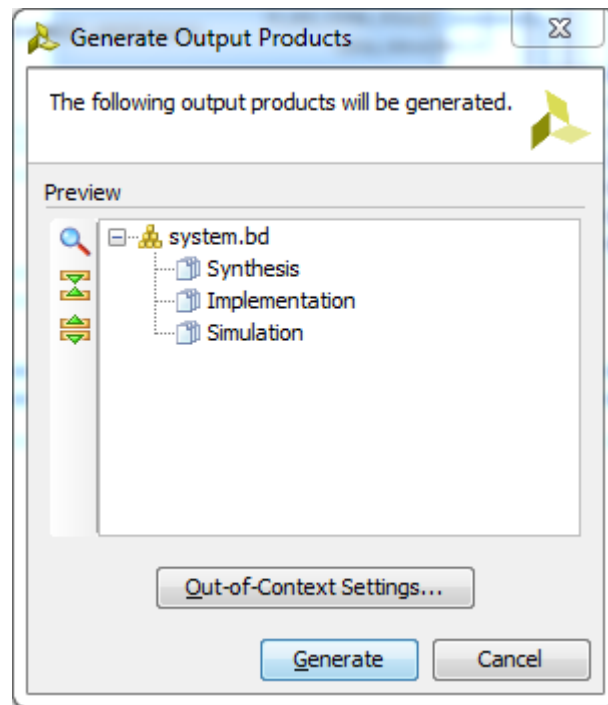

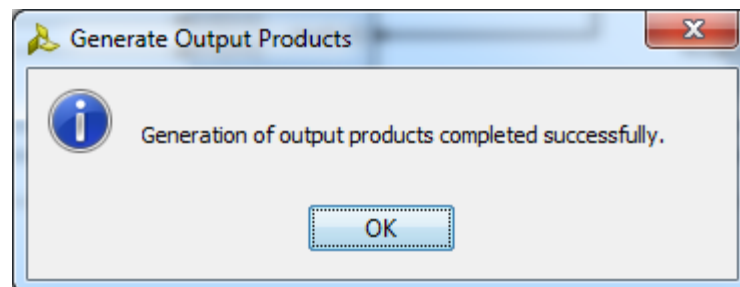

Figure 28 Flow Navigator pane

The “Generate Output Products” dialog box shown in Figure 29 will appear. Click on the “Generate” button.

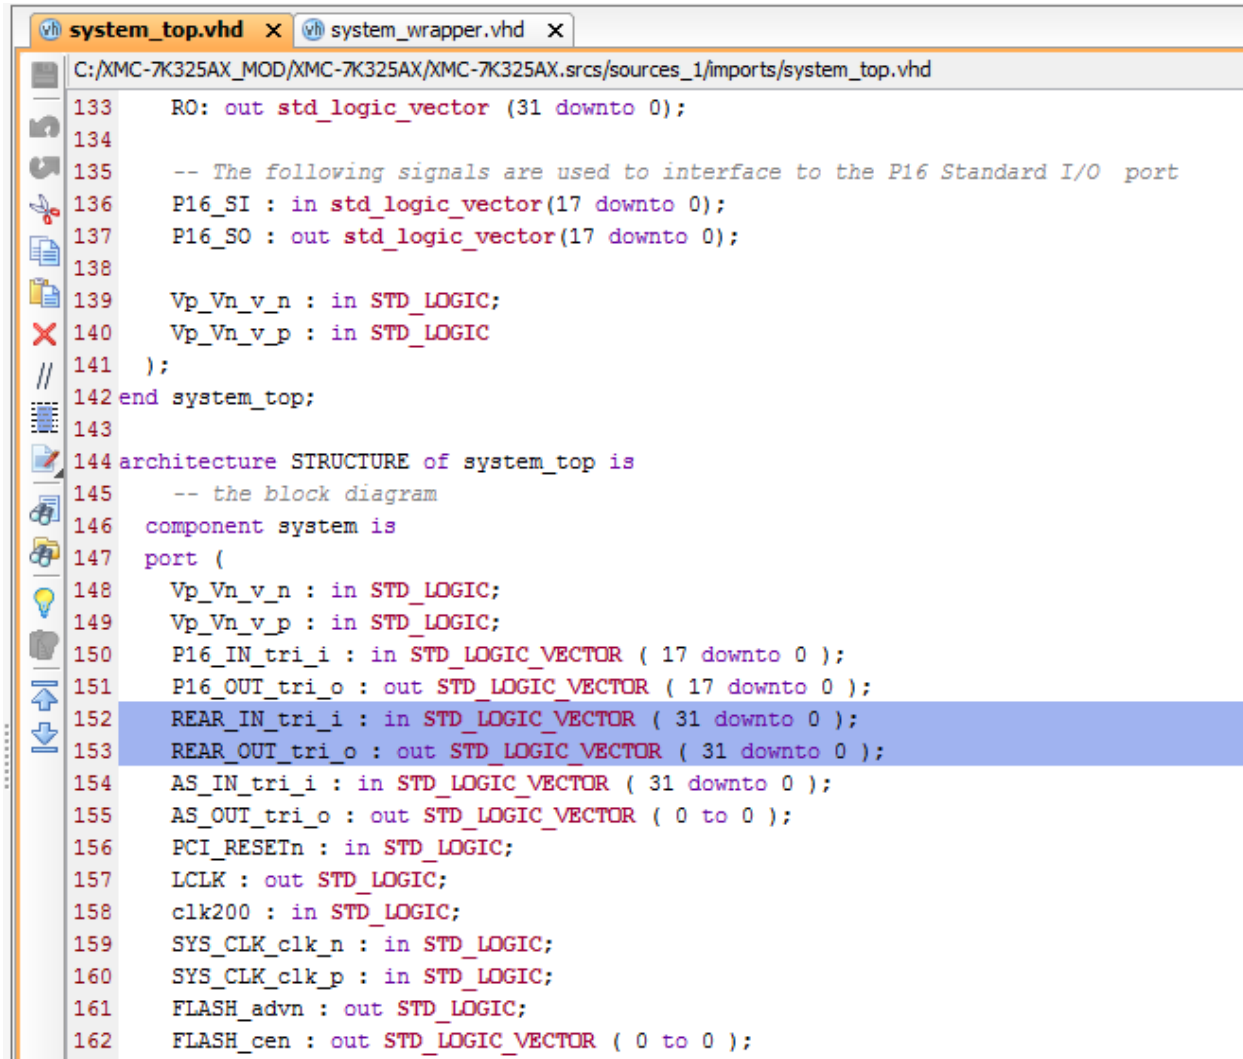

**Figure 29 Generate Output Products Dialog**

Vivado will display the following pop-up on completion:

The system component and its instantiation in the system\_top.vhd file must now be updated with changes made to the ports of the REAR\_IO block. Open the system\_wrapper.vhd file in C:/XMC-7K325AX\_MOD/XMC-7K325AX/XMC-7K325AX.srccs/sources\_1/bd/system/hdl to see the updated component definition. Prior to the update, the system component definition included ports labeled REAR\_IN\_tri\_i and REAR\_OUT\_tri\_o. Now the updated system component definition has REAR\_IO\_tri\_i, REAR\_IO\_tri\_o, and REAR\_IO\_tri\_t.

Open the system\_top.vhd file located in C:/XMC-7K325AX\_MOD/XMC-7K325AX/XMC-7K325AX.srscs/sources\_1/imports. Delete lines 152 and 153.

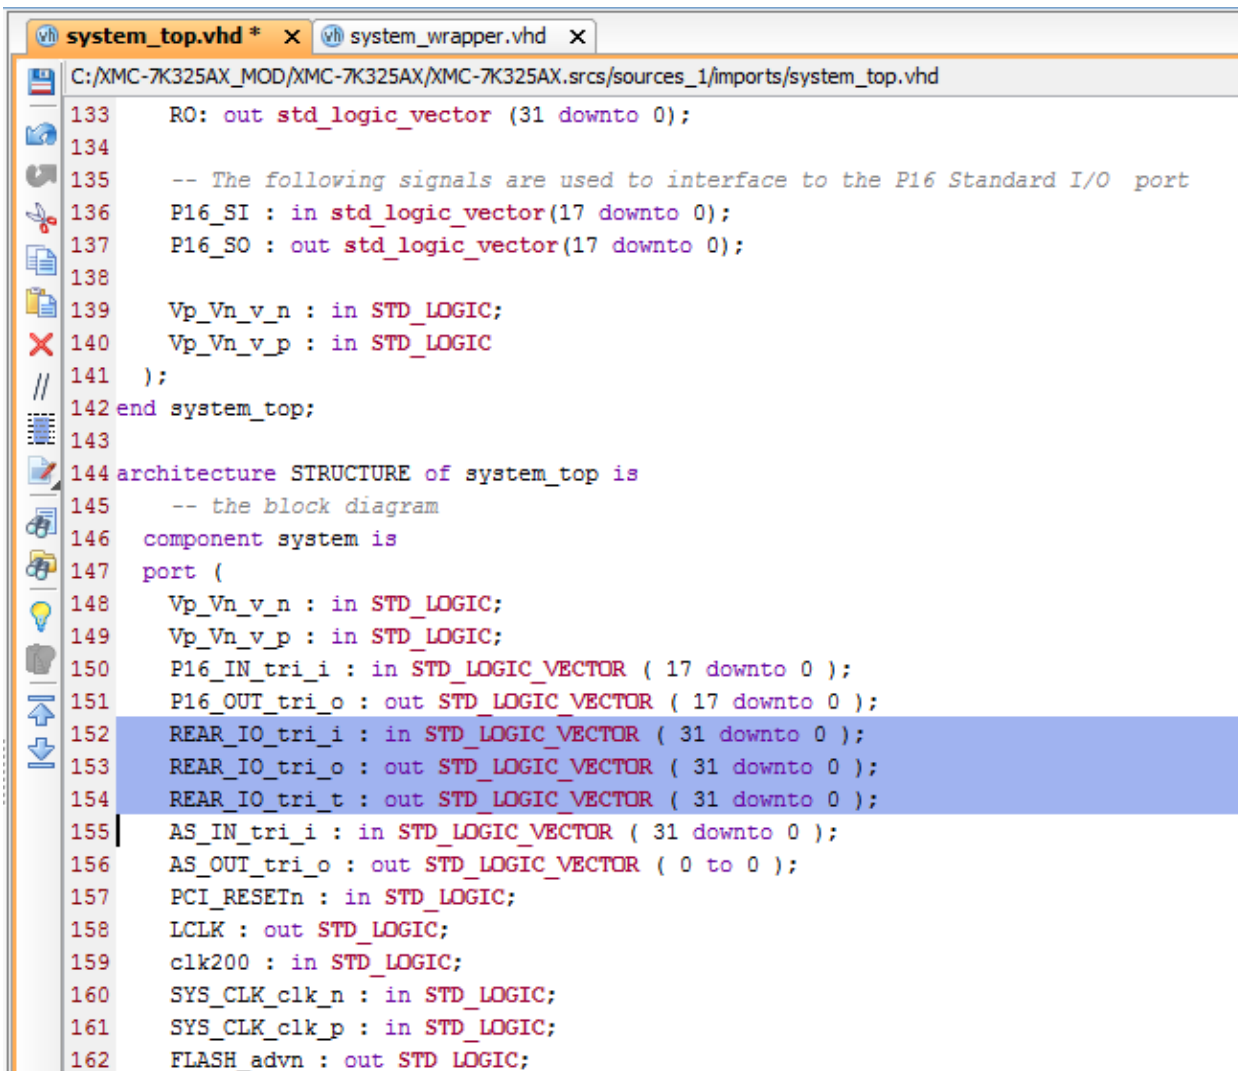

```

Select "Save File" from the "File" menu or type Cntrl-S to save the changes.

## Modify the Constraints File

The constraints file must be updated. Expand the Constraints file list by clicking of the “+” symbol left of “Constraints” in the “Sources” pane as shown.

Double-click on the XMC-7KxxxAX.xdc constraints file to open it.

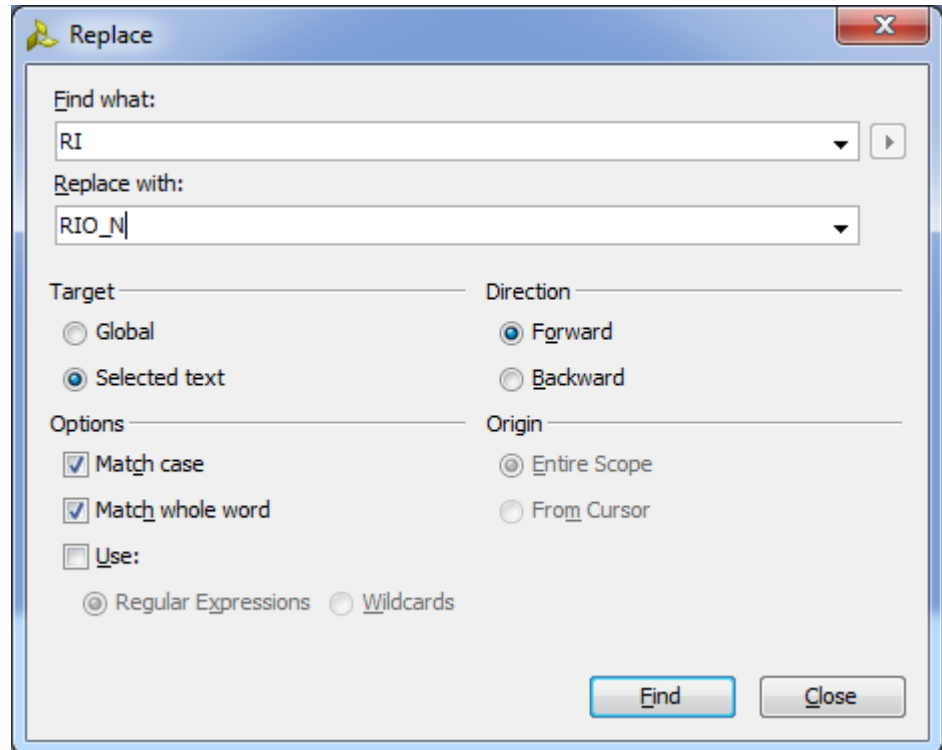

To change the single-ended signal names to differential signal names rename all of the signals labeled “RO” to “RIO\_P” in lines 194 to 323. Rename all of

the signals labeled “RI” to “RIO\_N” in lines 194 to 323 (only lines 194 thru 213 are shown in figure).

```

C:/XMC-7K325AX_MOD/XMC-7K325AX/XMC-7K325AX.srcs/constrs_1/imports/Constraints/XMC-7KxxxAX.xdc
194 set_property PACKAGE_PIN D13 [get_ports {RI[0]}]
195 set_property PACKAGE_PIN D12 [get_ports {RO[0]}]
196 set_property PACKAGE_PIN A18 [get_ports {RI[1]}]
197 set_property PACKAGE_PIN B18 [get_ports {RO[1]}]

203 set_property PACKAGE_PIN D11 [get_ports {RO[4]}]
204 set_property PACKAGE_PIN B19 [get_ports {RI[5]}]
205 set_property PACKAGE_PIN C19 [get_ports {RO[5]}]
206 set_property PACKAGE_PIN C22 [get_ports {RI[6]}]
207 set_property PACKAGE_PIN D22 [get_ports {RO[6]}]
208 set_property PACKAGE_PIN F22 [get_ports {RI[7]}]
209 set_property PACKAGE_PIN G22 [get_ports {RO[7]}]
210 set_property PACKAGE_PIN E16 [get_ports {RI[8]}]
211 set_property PACKAGE_PIN F15 [get_ports {RO[8]}]
212 set_property PACKAGE_PIN C16 [get_ports {RI[9]}]
213 set_property PACKAGE_PIN D16 [get_ports {RO[9]}]
  
```

Select lines 194 to 323. Type Cntrl-R to open the replace dialog box. Select options as shown. Click Find.

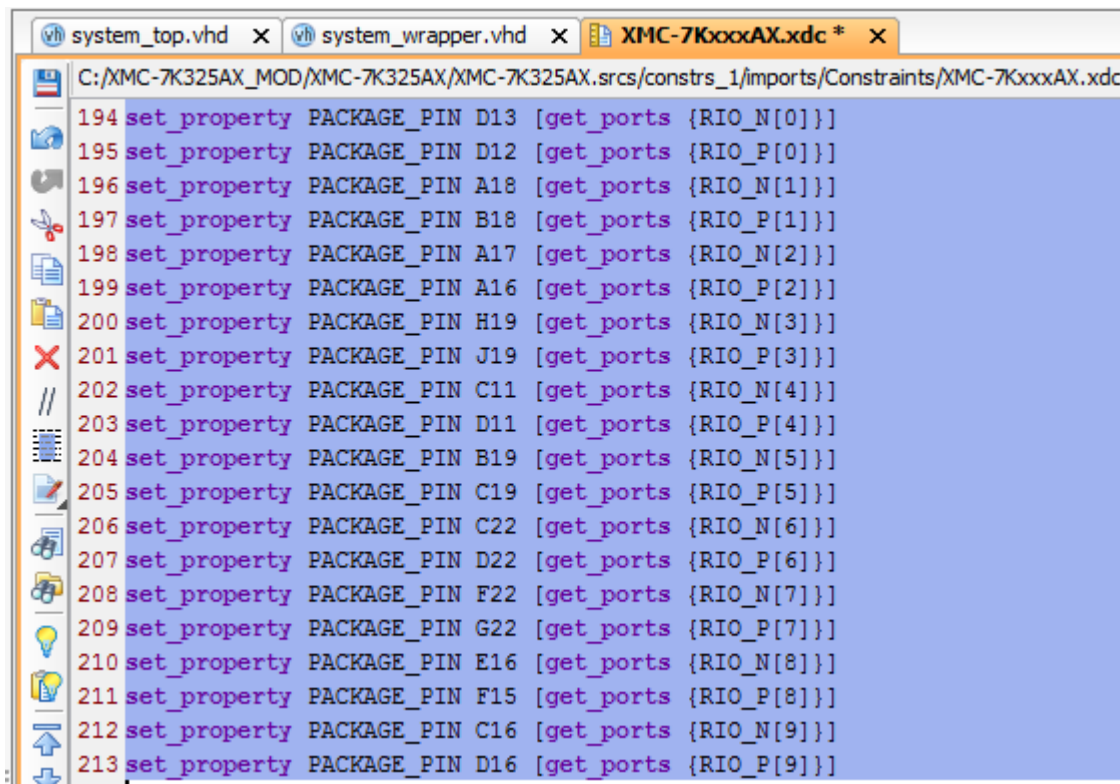

And then click All.

Result after editing.

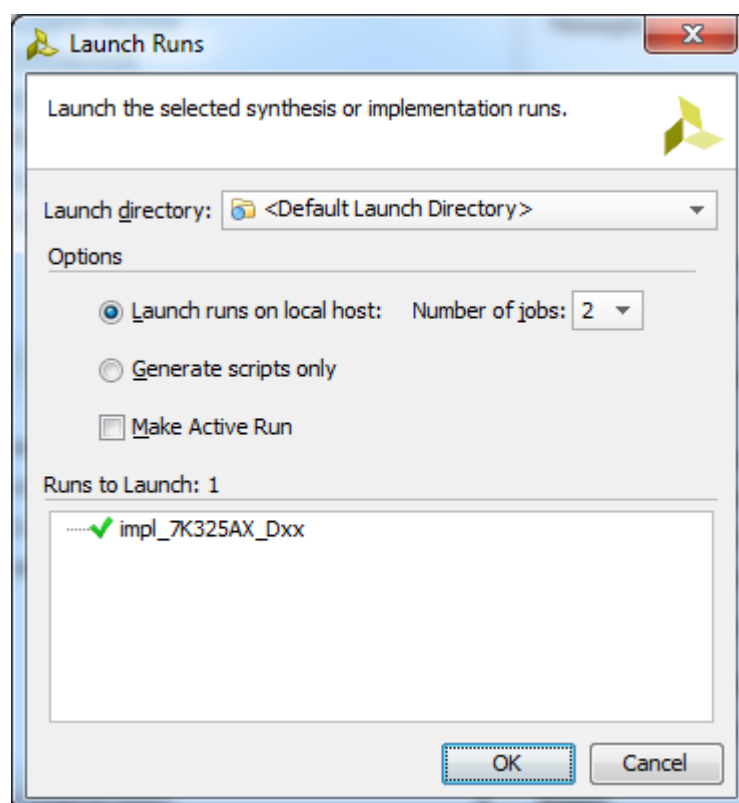

Select "Save File" from the "File" menu or type Cntrl-S to save the changes.

## Compile the Design

Compile the design by selecting the appropriate Design Run for the installed AXM module. For this example select the Dxx AXM module design run by right-clicking on impl\_7K325AX\_Dxx and then choosing "launch runs" from the pop-up menu.

Design Runs												
Name	Constraints	WNS	TNS	WHS	THS	TPWS	Failed Routes	LUT	FF	BRAM	DSP	
✓ synth_7K325AX_D01	constrs_AXM_Dxx							29.84	15.74	4.38	0.00	
✓ impl_7K325AX_D01	constrs_AXM_Dxx	0.18	0.00	0.04	0.00	0.00	0	27.45	13.83	4.38	0.00	
✓ synth_7K325AX_A75	constrs_AXM_A75							30.53	16.06	4.38	0.00	
✓ impl_7K325AX_A75	constrs_AXM_A75	0.11	0.00	0.04	0.00	0.00	0	28.64	14.49	7.98	1.90	
✓ synth_7K325AX_Dxx (active)	constrs_AXM_Dxx							29.87	15.75	4.38	0.00	
✓ impl_7K325AX_Dxx (active)	constrs_AXM_Dxx	0.15	0.00	0.04	0.00	0.00	0	27.46	13.84	4.38	0.00	

The following dialog box appears. Click OK

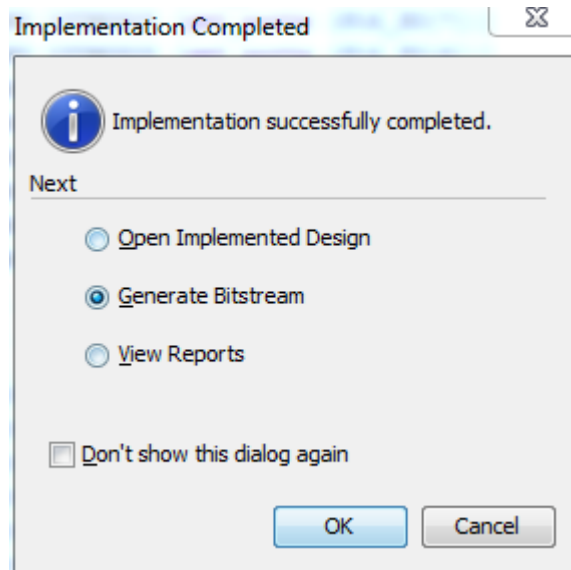

Click OK a second time.

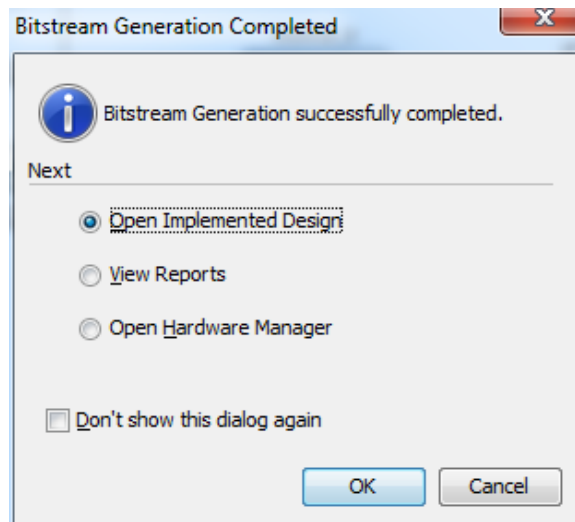

## Generate Bitstream

When the synthesis and implementation steps are complete Vivado displays the following dialog box. Click OK to proceed with generating the bitstream.

When bitstream generation is complete, the following dialog box is displayed. Click on the OK button if you want to view implementation details, otherwise click on the Cancel button and proceed to the next step.

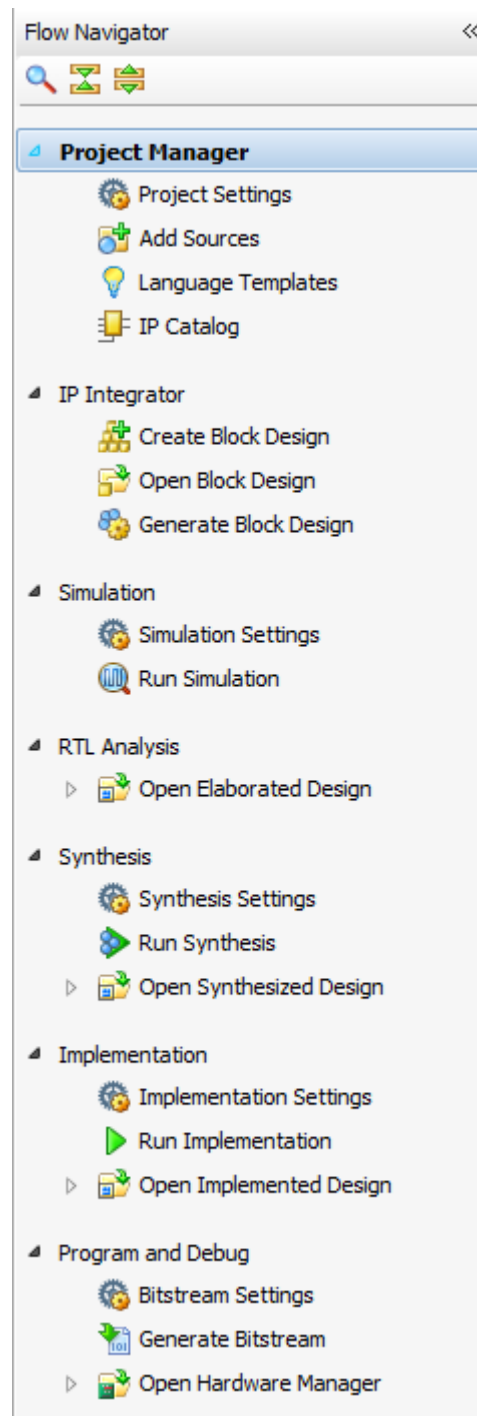

The flash image (.mcs) file will be created in the implementation directory for the current run. The flash image file will eventually be loaded into Flash memory. For this example, the file C:\XMC-7K325A\_MOD\XMC-7K325AX.runs\impl\_7K325AX\_Dxx\7K325AX.mcs will be created.

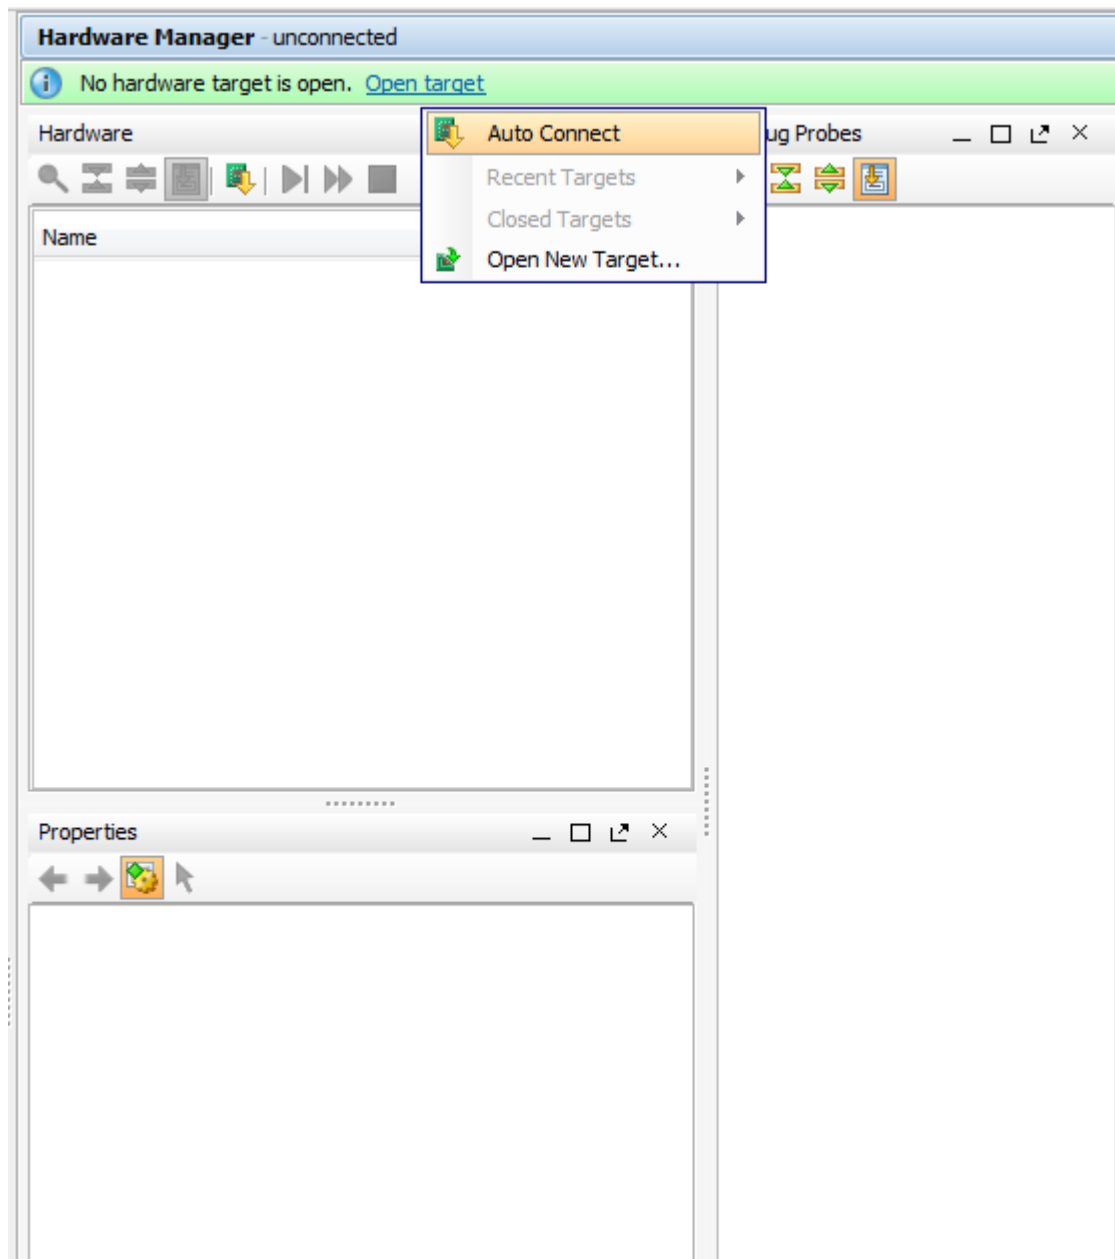

If a Xilinx programming adapter is attached to a powered XMC-7K325AX board through a JTAG connection then the Flash can be programmed at this

time. (The Flash can also be programmed from the host PC over the PCIe bus if the Acromag example firmware is currently loaded in the FPGA. Skip to next step).

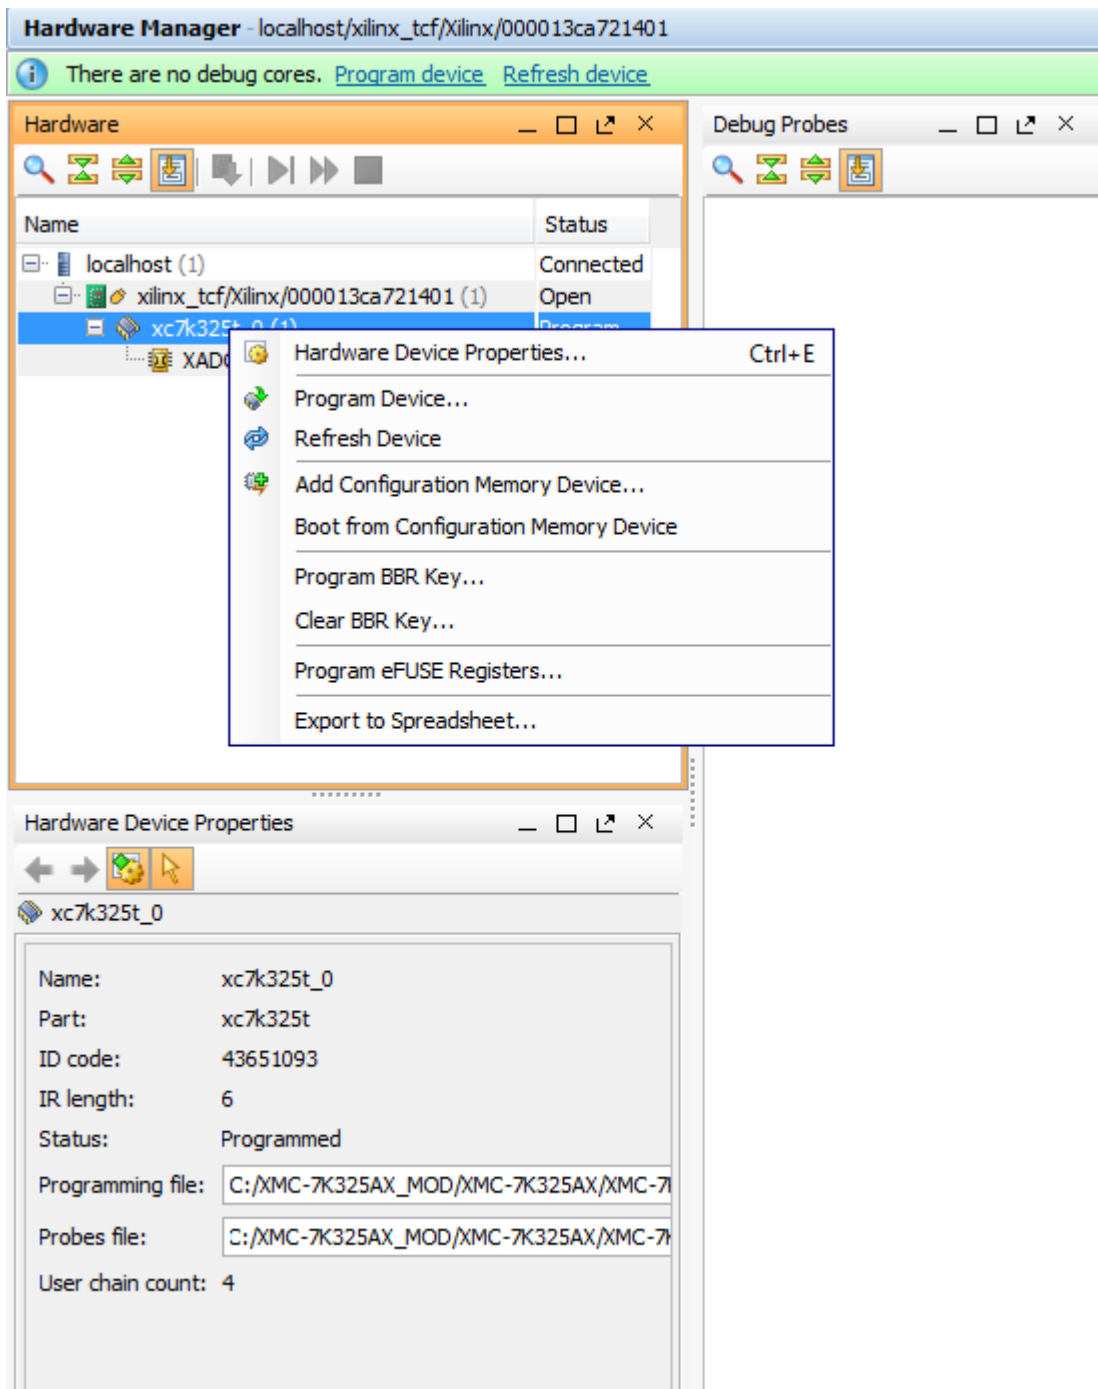

Select “Open Hardware Manager” under “Program and Debug” in the “Flow Navigator” pane.

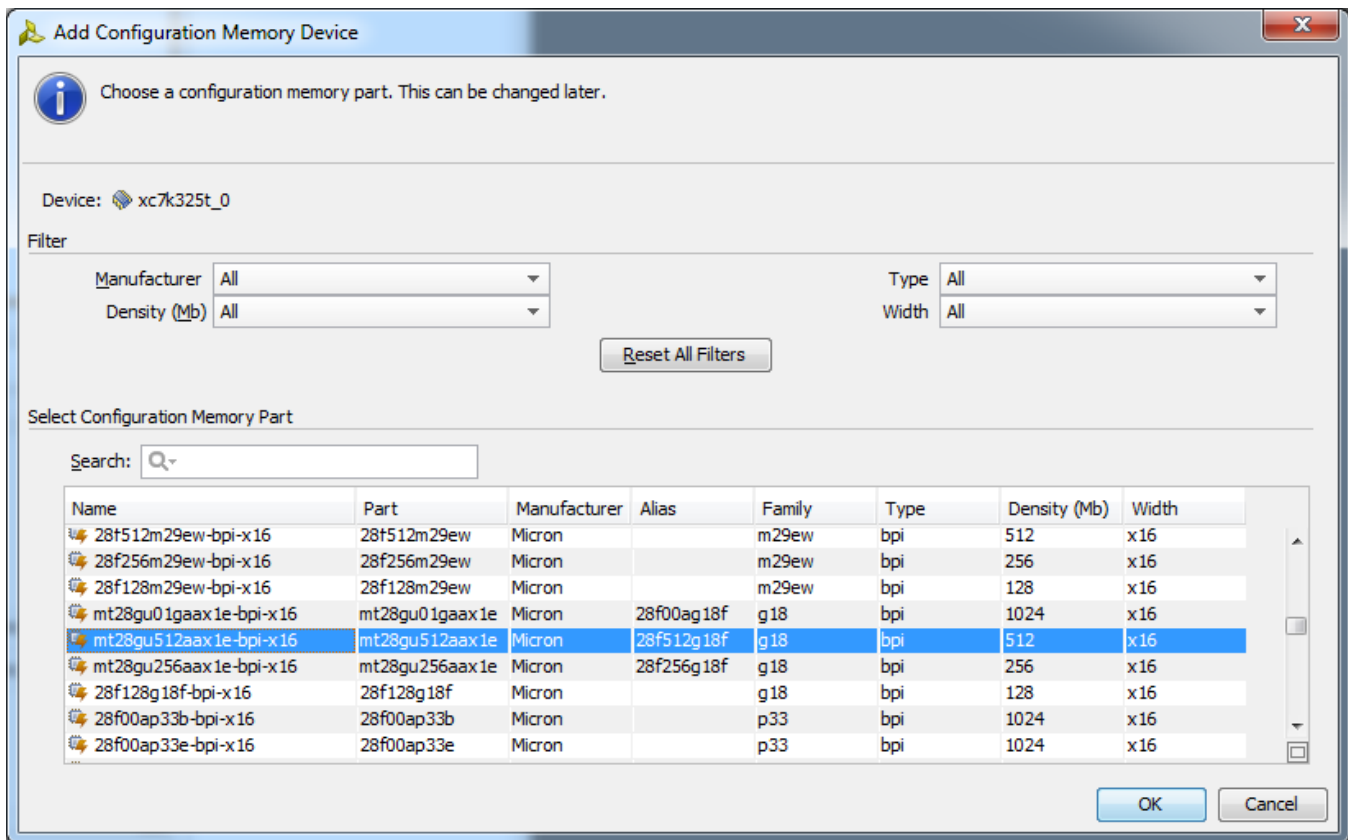

Click on “OpenTarget” and then “Auto Connect”.

Right-click on “xc7k325t\_0(1)” and then select “Add Configuration Memory Device...”.

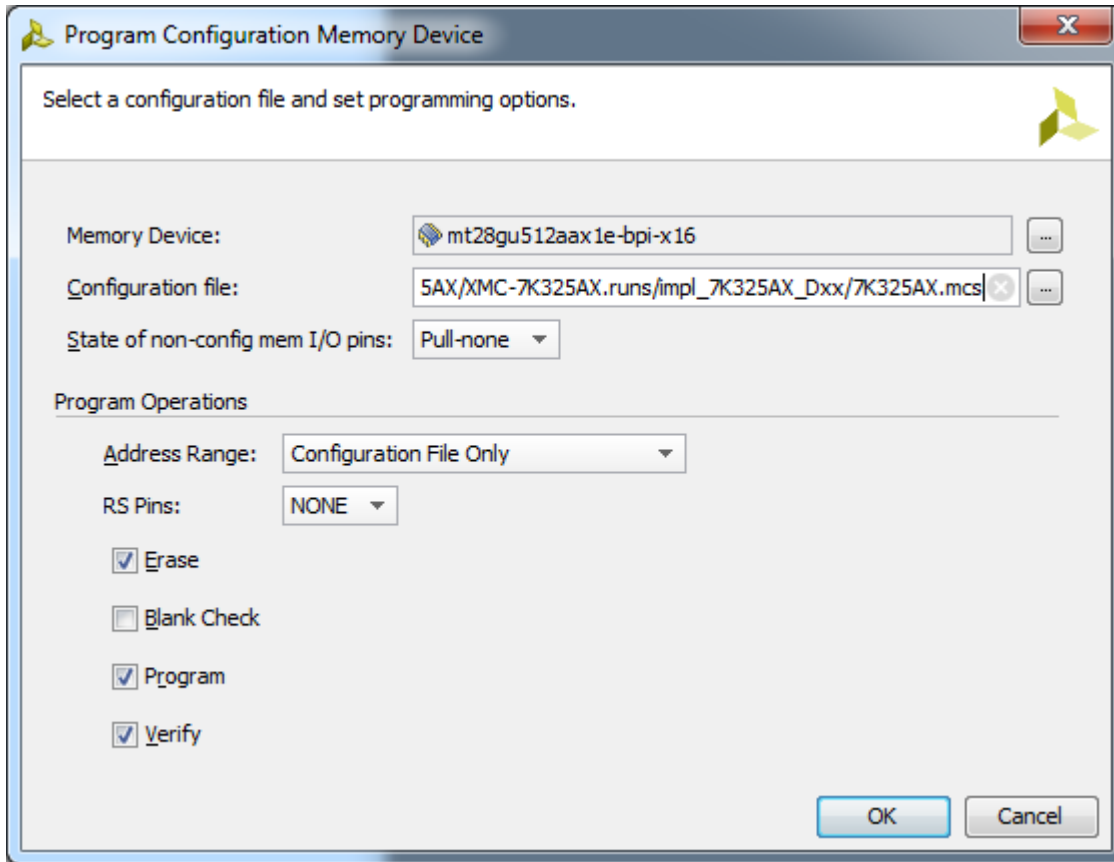

The following window appears. Scroll to select the “mt28gu512aax1e-bpi-x16” device. Click “OK”.

The following dialog box appears. Click “OK”.

The following dialog box appears. Browse to select the flash image file (.mcs) that you want to write to flash. Click "OK" to write the file to flash.

The flash write progress is displayed.

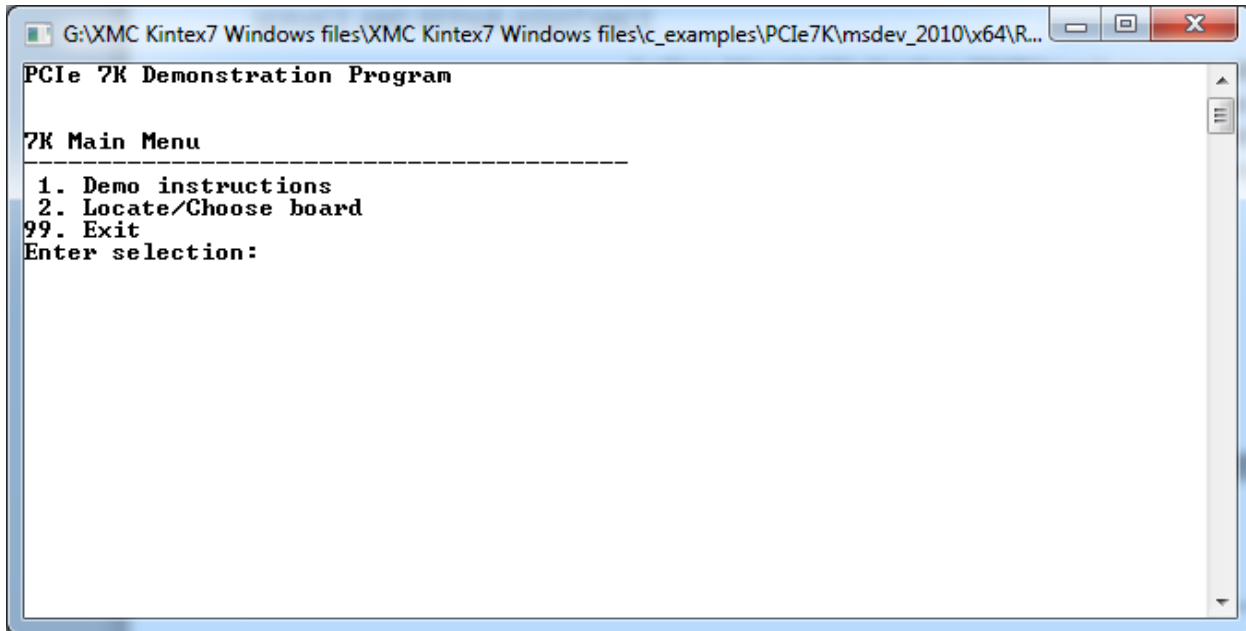

When the write operation is complete the following window is displayed.

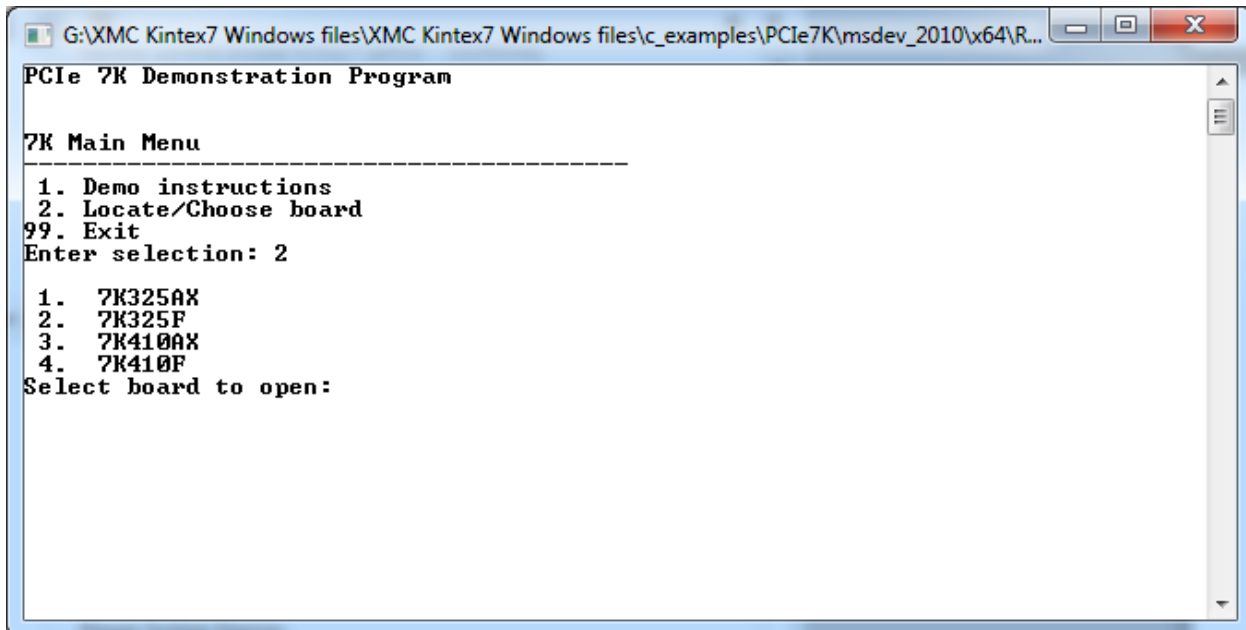

## Write Configuration File to Flash

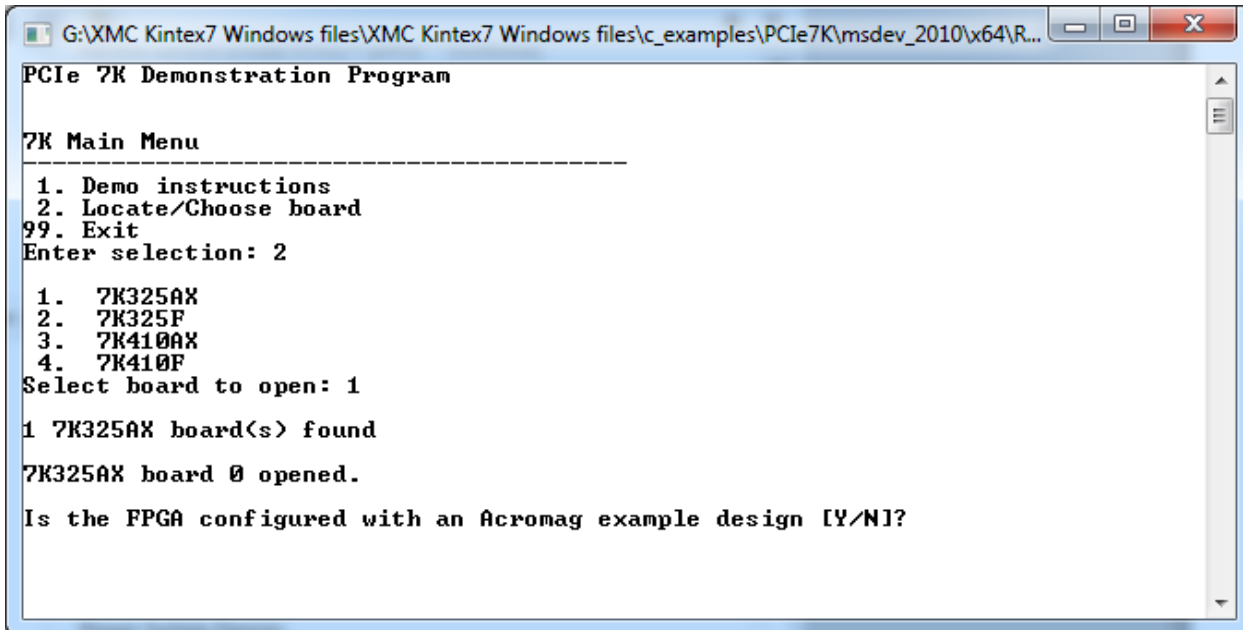

Start the PCIe7KDemo program to program the FPGA from the host PC. The following screen is displayed. Type "2" to locate the board to be programmed.

The following screen is displayed. Type "1" to select the 7K325AX XMC module.

The following screen is displayed. Type "Y".

```

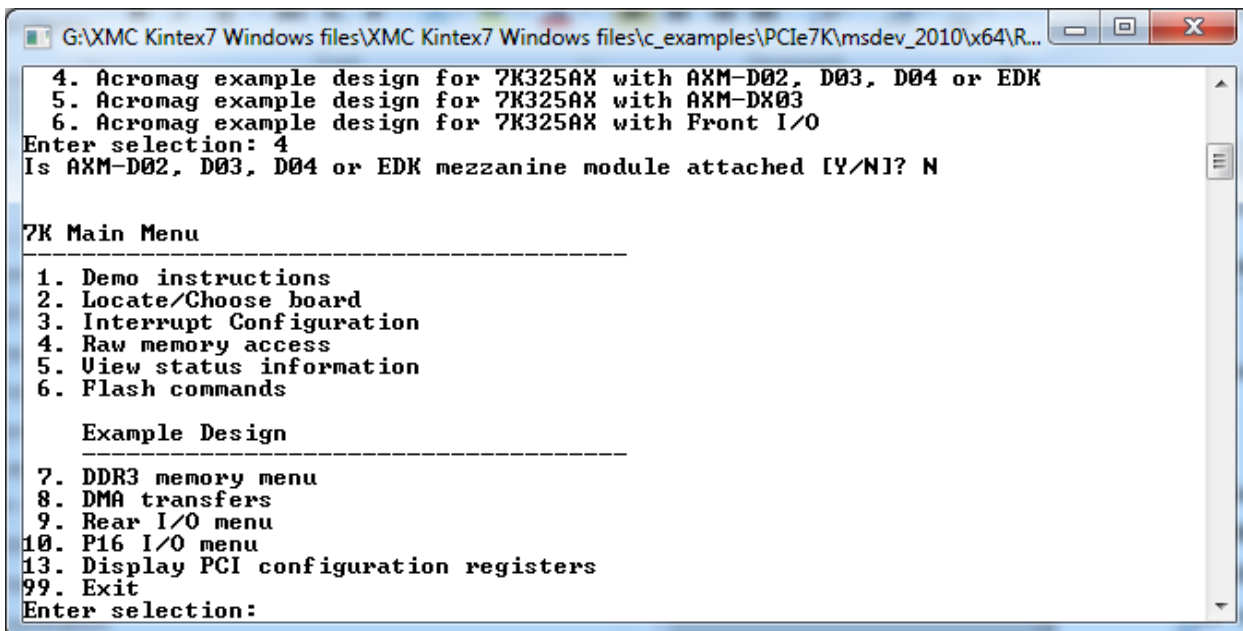

G:\XMC Kintex7 Windows files\XMC Kintex7 Windows files\c_examples\PCIe7K\msdev_2010\x64\R...

22. Compare file to flash
99. Return to main menu
Enter selection:
  
```

You must cycle the power to the XMC-7K325AX module in order to load the updated configuration file into the FPGA.

## 9. SERVICE AND REPAIR

### SERVICE AND REPAIR ASSISTANCE

Surface-Mounted Technology (SMT) boards are generally difficult to repair. It is highly recommended that a non-functioning board be returned to Acromag for repair. The board can be damaged unless special SMT repair and service tools are used. Further, Acromag has automated test equipment that thoroughly checks the performance of each board.

Please refer to Acromag's Service Policy Bulletin or contact Acromag for complete details on how to obtain parts and repair.

### PRELIMINARY SERVICE PROCEDURE

Before beginning repair, be sure that all of the procedures in Section 3, Preparation For Use, have been followed. Also, refer to the documentation of your carrier board to verify that it is correctly configured. Replacement of the carrier and/or XMC module with one that is known to work correctly is a good technique to isolate a faulty board.

**CAUTION: POWER MUST BE TURNED OFF BEFORE REMOVING OR INSERTING BOARDS**

### WHERE TO GET HELP

If you continue to have problems, your next step should be to visit the Acromag worldwide web site at <http://www.acromag.com>. Our web site contains the most up-to-date product and software information.

Go to the "Support" tab to access:

Application Notes

Frequently Asked Questions (FAQ's)

Product Knowledge Base

Tutorials

Software Updates/Drivers

An email question can also be submitted from within the Knowledge Base or directly from the "Contact Us" tab.

Acromag's application engineers can also be contacted directly for technical assistance via telephone or FAX through the numbers listed below. When needed, complete repair services are also available.

Phone: 248-624-1541

Fax: 248-624-9234

Email: [solutions@acromag.com](mailto:solutions@acromag.com)

## 10.SPECIFICATIONS

### PHYSICAL

Length .....	149.0 mm (5.866 in)
Width .....	74.0 mm (2.913 in)
Stacking Height .....	10.0 mm (0.394 in)
Weight XMC-7A200.....	110 g
Weight XMC-7A200CC .....	115 g
Weight XMC-7K325AX .....	123 g
Weight XMC-7K325CC.....	117 g
Weight XMC-7K410AX .....	123 g
Weight XMC-7K410CC.....	117 g
Weight XMC-7K325F .....	148 g
Weight XMC-7K410F .....	148 g

### POWER

Power will vary dependent on the application. Power values are given for the Acromag example design with the AXM-EDK board installed on the AX models.

#### **XMC-7A200/CC Models**

+3.3 Volts .....	2.1 A
+3.3 Aux Volts .....	17 uA
+12/5 Volts (VPWR) .....	150 mA @ +12V
+12 Volts .....	0.1 mA
-12 Volts .....	0 mA

#### **XMC-7K325AX/CC Models**

+3.3 Volts .....	2.32 A
+3.3 Aux Volts .....	17 uA
+12/5 Volts (VPWR) .....	220 mA @ +12V
+12 Volts .....	0.1 mA
-12 Volts .....	0 mA

#### **XMC-7K410AX/CC Models**

+3.3 Volts .....	2.32 A
+3.3 Aux Volts .....	17 uA
+12/5 Volts (VPWR) .....	220 mA @ +12V
+12 Volts .....	0.1 mA
-12 Volts .....	0 mA

#### **XMC-7K325F**

+3.3 Volts .....	3 A
+3.3 Aux Volts .....	17 uA
+12/5 Volts (VPWR) .....	250 mA @ +12V
+12 Volts .....	0.1 mA
-12 Volts .....	0 mA

**XMC-7K410F**

+3.3 Volts .....	3.2 A
+3.3 Aux Volts .....	17 uA
+12/5 Volts (VPWR) .....	250 mA @ +12V
+12 Volts .....	0.1 mA
-12 Volts .....	0 mA

**PCIe BUS COMPLIANCE**

Specification.....	This device meets or exceeds all written PCI Express specifications per revision 2.1 dated March 4, 2009. Note: PCIe Gen 2 signal rates exceed the rated bandwidth of the XMC connectors.
--------------------	---

**ENVIRONMENTAL**

Operating Temperature .....	XMC-7A200 -40°C to +55°C <sup>6</sup> XMC-7A200CC -40°C to +75°C cold-plate <sup>7</sup> XMC-7K325AX -40°C to +45°C <sup>8</sup> XMC-7K410AX -40°C to +40°C <sup>9</sup> XMC-7K325CC -40°C to +70°C cold-plate <sup>10</sup> XMC-7K410CC -40°C to +70°C cold-plate <sup>11</sup> XMC-7K325F -40°C to +55°C <sup>12</sup> XMC-7K410F -40°C to +55°C <sup>13</sup>
Relative Humidity.....	5-95% non-condensing
Storage Temperature .....	-55 to +125°C
Non-Isolated.....	The PCIe bus and the XMC module commons have a direct electrical connection. As such unless the XMC module provides isolation between the logic and user I/O signals, the user I/O signals are not isolated from the PCIe bus.
Radiated Field Immunity.....	Complies with IEC61000-4-3 class A
Surge Immunity.....	Not required for signal I/O per European Norm EN61000-6-1

<sup>6</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

<sup>7</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R) between the carrier cold plate and the XMC module heatsink.

<sup>8</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

<sup>9</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

<sup>10</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R) between the carrier cold plate and the XMC module heatsink.

<sup>11</sup> Tested on Acromag VPX4820-CC carrier with thermal interface material (Berquist Gap Pad 1500R) between the carrier cold plate and the XMC module heatsink.

<sup>12</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

<sup>13</sup> Tested on Acromag VPX4820 carrier with 500 LFM airflow

## Electric Fast Transient Immunity

Complies with IEC61000-4-4 class A

Radiated Emissions ..... Complies with CISPR 16-2-3 class A

Electrostatic Discharge ..... Complies with IEC6100-4-2 Level 2

## Conducted Radio Frequency Interference

Complies with IEC6100-4-6 class A

## Certificate of Volatility

## 11. Accessories

### XMC-7K325F and XMC-7K410F Accessories

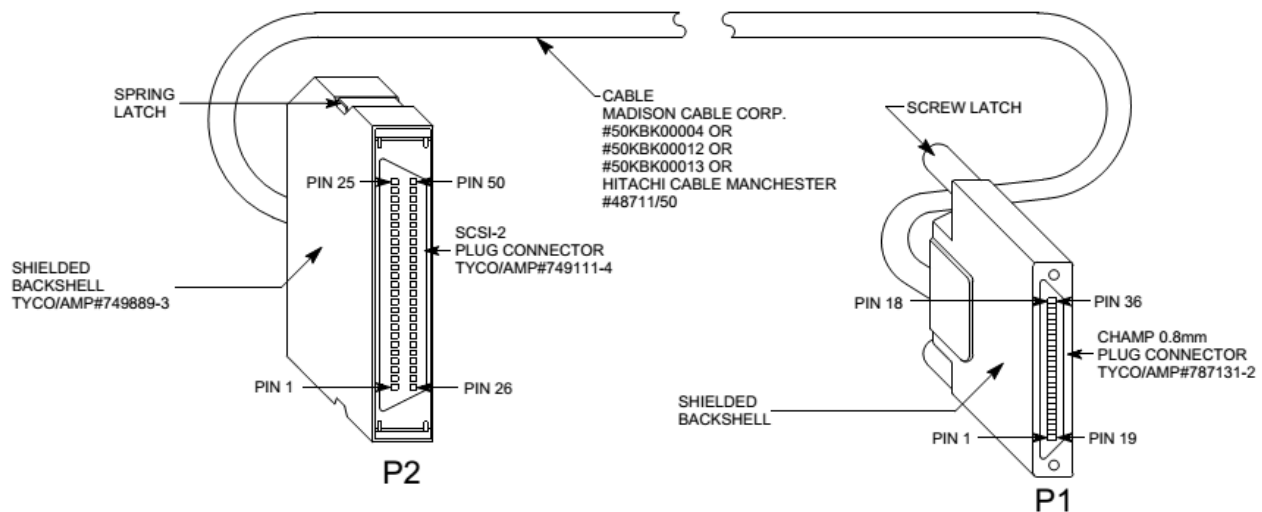

#### VHDCI Cable

Acromag offers a cable that brings the 36 pins of the VHDCI front I/O connector out to a 50 pin SCSI-2 connector. The Acromag part number is 5025-921. See Table 5 Front VHDCI Field I/O Pin Connections.

The cable assembly uses a 25 paired round shielded/jacketed flat cable (50 conductors total), with a 50 position SCSI-2 male connector (with spring latch) at one end and a 36 position CHAMP 0.8mm plug connector (with screw latch) at the other end. The cable length is 2 meters (6.56 feet).

#### Specifications

Voltage .....	30VAC
Current .....	1.5 Amperes for single circuit
	0.5 amperes at 10°C
	0.3 Ampere 100% energized (per Champ 0.8mm Connector)
Operating Temperature Range .....	-40°C to 85°C
Length .....	2m (6.56 feet)

## SFP+ Direct Attach Cable

Acromag offers a 1 meter cable that connects one SFP+ port to another SFP+ port. This cable supports speeds up to 10 Gbps. The Acromag part number is TAPCABLE1M.

### Specifications

Length ..... 1 m  
 Gender ..... Male-Male  
 Current ..... 0.5A (max per contact)  
 Voltage ..... 30V (max)  
 Shielded..... yes

WIRING DIAGRAM

### 1000BASE-T Copper SFP Transceiver

Acromag offers a SFP Transceiver that is compatible with the Gigabit Ethernet and 1000BASE-T standards as specified in IEEE Std 802.3. It is RoHS compliant and lead-free. The Acromag part number is 5028-455.

#### Specifications

Operating Temperature Range ..... -40°C to 85°C

Connector..... RJ45

### 2.125 Gb/s Short-Wavelength SFP Transceiver

Acromag provides 2.125 Gb/s Short Wavelength SFP Transceiver that is compatible with the Gigabit Ethernet standard as specified in IEEE Std 802.3 and Fibre Channel FC-P1-2 Rev. 5.0. It is RoHS compliant and lead-free. The Acromag part number is 5028-452.

#### Specifications

Connector.....	Duplex LC
Bit Rate.....	Up to 2.125 Gb/s
Cable lengths.....	500m on 50/125µm Multi-Mode Fiber 300m on 62.5/125µm Multi-Mode Fiber
Laser .....	850 nm Oxide VCSEL
Power .....	less than 500 mW
Operating temperature range .....	-40°C to 85°C

#### Applications

1.25 Gb/s 1000Base-SX Ethernet  
Dual Rate 1.063/2.125 Gb/s Fibre Channel

## 12.Revision History

---

Release Date	Version	EGR/DOC	Description of Revision
27-JAN-15	A	JCL/ARP	Initial release.
15-MAY-15	B	JCL/ARP	Added XMC-7A200-LF, XMC-7A200CC-LF, XMC-7K325F-LF and XMC-7K410F-LF models
20-AUG-15	C	JCL/ARP	Added CE compliance statement to specifications section.
