With the CNT-81 series of counters and analyzers, Pendulum now offers the ultimate tools for measurement, analysis and calibration of Frequency, Time Interval or Phase, whether in test systems, on the R&D bench, in the calibration lab or out in the field (portable calibration). The series comprises 2 models; the ultra-high performance CNT-81 and the ultimate CNT-81R including a built-in Rubidium time-base reference.

Frequency calibration

The CNT-81 and CNT-81R can directly calibrate any application specific frequency up to 8 GHz. They are ideal for calibrating e.g. the timebase oscillator of other instruments, like frequency counters and synthesisers.

The Rubidium timebase of CNT-81R allows frequency calibration of even the highest possible specified oven oscillators. For a total uncertainty of 10^{-10}, just connect the unknown frequency to the counters input and wait for a second.

Each individual 1s-measurement has a $5x10^{-11}$ resolution. The built-in statistics averaging improves resolution further, and the std dev indicator gives added information about the stability of the unknown frequency.

Time Interval calibration

For the calibration of time-intervals the CNT-81 provides leading performance due to the fast 50 ps single shot time resolution (1 ps averaged) and the high trigger level resolution of 1.25 mV.

The systematic start-stop channel difference is only 500 ps, which can be further reduced by calibrating the input channel difference.

Phase calibration

With CNT-81 you can measure phase differences on signals of up to 160 MHz with a resolution better than 0.01° (below 30 MHz). This gives you outstanding resolution in measurements like laser positioning and calibration of phase meters. Calibration procedures exist that provide outstanding accuracy, with an uncertainty below 0.1°.

Ideal for fast test systems

In manufacturing test systems two things are important; EMC-immunity and speed. CNT-81 offers excellent EMC-shielding and the highest throughput for any commercially available counter. The speed is impressive 8000/s to internal memory, and 250/s for individually triggered measurements via GPIB. Up to 20 complex measurement set-ups can be locally stored in the counter's non-volatile set-up memory and instantly recalled via a short bus command. This enables new measurement tasks to be executed one after the other at a very-high rate. A complete cycle "setup-measure-transfer" takes less than 8 ms.

The two counters comply of course to SCPI, which facilitates easy updating of new test hardware without the penalty of time-consuming SW-rewriting.

Modulation Domain Analysis

The analysis PC-SW *TimeView* converts the CNT-81/CNT-81R to a high performance modulation domain analyzer. In the modulation domain you can view rapid frequency changes vs. time, e.g. modulation, sweep, freqiency setting, channel hopping etc.

The 16-bit DOS program is standardly included with all CNT-81/81R.

The 32-bit Windows program is an optional accessory (option 29).

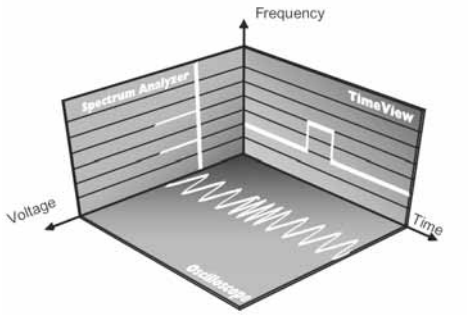

Figure 1: The modulation domain (f vs. t) complements the time (V vs. t) and the frequency (V vs. f) domains

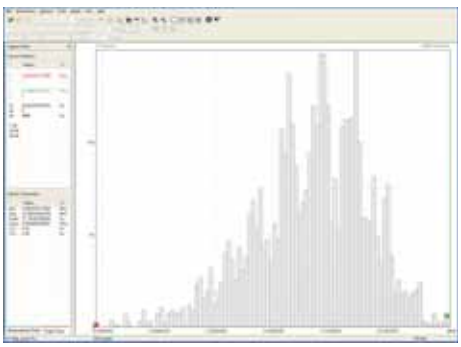

Figure 2: Jitter (rms and peak-peak) and noise is quantified in distribution histograms.

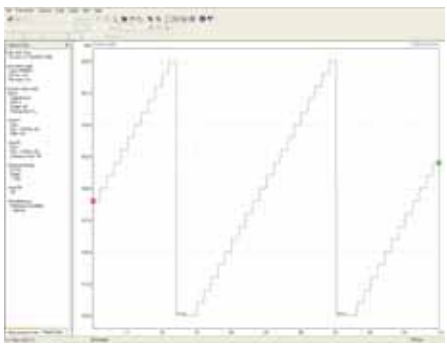

Figure 4: Linearity of frequency sweep can be verified in the modulation domain (frequency vs. time).

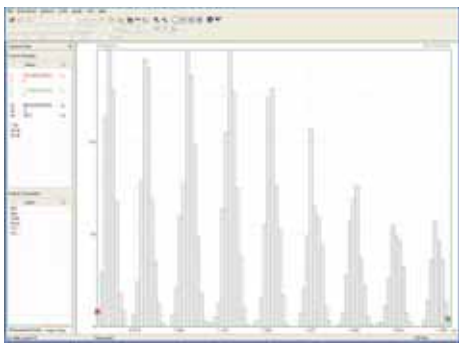

Figure 6: The 9 different pulse width clusters, corresponding to the 9 different pit lenghts (T3-T11) in a CD-recording.

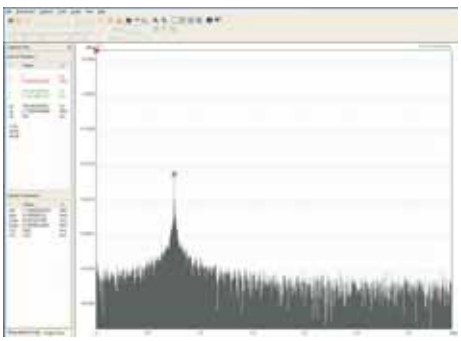

Figure 3: The FFT-diagram reveals the modulation frequency, whether intended or unwanted.

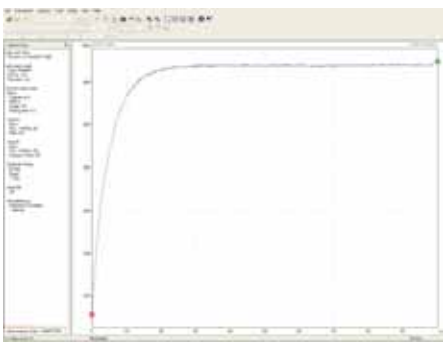

Figure 5: Repetitive samplings gives an effective sampling rate of 10 Msa/s. This VCO has a frequency switching time of approx. 10.7 us.

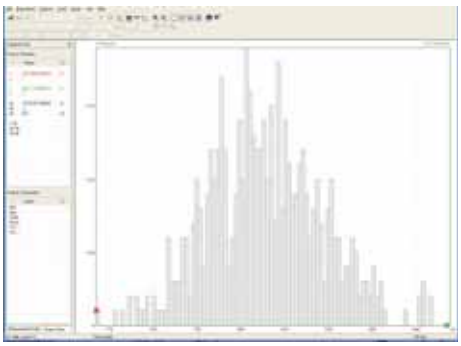

Figure 7: Zoom in on T3-cluster displays an rms-jitter of 13 ns, which is OK for an audio CD.
