5-1 RECEIVER CIRCUITS

RF CIRCUITS

The antenna switching circuit toggles between the receive (RX) line and transmit (TX) line. RF amplifier amplifies the received signals within the frequency coverage.

Received signals from the antenna are passed through Low Pass filter (LPF; L40, C369, C370), TX power detector (D47, D49, D51) and another LPF (L38, L39, L45, C343, C345, C349, C350, C356, C357), then applied to the antenna switching circuit (D38, D39, L37, C337, C346).

The received signals are passed through the antenna switching circuit as an LPF (L37, C337, C346), LPF (L35, C322, C322, C323, C336) and two-staged tuned Bandpass Filter (BPF; D34, L32, C299, C300 and D31, L31, C278, C279), then applied to the RF amplifier (Q31).

The amplified signals are passed through another two-staged tuned BPF (D27, L28, C260–C263, C242 and D26, L26, C219, C220, C240) and applied to the 1st mixer (IC10; pins 4, 5, L18, L19, L24).

1ST IF CIRCUITS

The amplified received signals from the RF circuit are converted into the 1st IF signal, filtered and amplified at the 1st IF circuits.

The received signals from the RF circuits are mixed with 1st Local Oscillator (LO) signal from the RX VCOs, to be converted into the 1st IF signal. The converted 1st IF signal is amplified by 1st IF amplifier (Q50). The amplified 1st IF signal is passed through the 1st IF filter (FI3 for analog mode, FI4 for digital mode) via filter switches (Q20, D21, D66, D67 on input side; D6, D68, D69 on output side) to suppress unwanted signals. The filtered 1st IF signal is amplified by another 1st IF amplifier (Q12), then applied to the 2nd IF circuits.

2ND IF CIRCUITS

The 1st IF signal is converted into the 2nd IF signal, amplified and demodulated in the IF IC.

The 1st IF signal from the 1st IF amplifier (Q12) is applied to the IF IC (IC5, pin 16). The applied signal is converted into the 2nd IF signal by being mixed with the 2nd LO signal from X1 via tripler (Q3, L3, L2, C32–C35).

The converted 2nd IF signal is output from pin 3, and passed through the 2nd IF filter (FI1). The filtered 2nd IF signal is passed through (bypassed) another 2nd IF filter (FI2) via filter switches (D1 on input side; D2 on output side). The filtered signal is then applied to the IF IC (IC5, pin 5), and amplified by 2nd IF amplifier. The amplified signal is FM-demodulated by quadrature detector (IC5, pins 10, 11; X3).

The demodulated AF signals are output from pin 9, then applied to the AF circuits.

AF CIRCUITS

The demodulated AF signals from the IF IC are amplified and filtered at AF circuits.

This transceiver employs the base band IC for audio signal processing for both transmit and receive. The base band IC is an audio processor and composed of pre-amplifier, compressor, expander, scrambler, etc. in its package.

The demodulated AF signals from IF IC (IC5, pin 9) are passed through Digital/Analog switch (IC8, pins 2, 15), and applied to the base band IC (IC2, pin 23).

The applied AF signals are amplified at the amplifier section and level adjusted at the volume controller section, then suppressed unwanted 3 kHz and higher audio signals at LPF. The filtered AF signals are applied (bypassed) the TX/RX HPF, scrambler, de-emphasis sections in sequence.

The TX/RX HPF filters out 250 Hz and lower audio signals, and the de-emphasis circuit obtains -6 dB/oct of audio characteristics. The expander expands the compressed audio signals and also noise reduction function is provided.

The AF signals are then level adjusted at the volume controller section and amplified at the amplifier section, then output from pin 20 (IC2).

• 2nd IF AND DEMODULATOR CIRCUITS

The processed AF signals from the base band IC (IC2) are passed through the AF mute switch (IC8, pins 3, 4) and D/A converter (IC6, pins 15, 16) for level adjustment. The level adjusted AF signals are amplified by AF amplifier (IC22).

The amplified AF signals are then;

- Output from D-sub 25 pin connector (CONNECT UNIT; J602).
- or
- Buffer-amplified by Q49, then applied to connected microphone via FRONT UNIT.
- or
- Applied to the AF power amplifier (IC21, pin 1) to obtain AF output power level, then applied to the internal/external speaker via external speaker jack (J7).

SQUELCH CIRCUITS

<NOISE SQUELCH>

The squelch mutes the AF output signals when no RF signals are received. By detecting noise components (30 kHz and higher signals) in the demodulated AF signals, the squelch circuit toggles the AF power amplifier ON and OFF.

A portion of the demodulated AF signals from the IF IC (IC5, pin 9) are applied to the D/A converter (IC6, pin 1) for level adjustment (squelch threshold adjustment). The level-adjusted AF signals are output from pin 2 and passed through the noise filter (IC5, pins 7, 8, R121–R124, C216–C218). The filtered noise signals are amplified the noise components only.

The amplified noise components are converted into the pulse-type signal at the noise detector section, and output from pin 13 as the “NOIS” signal. The “NOIS” signal is applied to the CPU (IC14, pin 113). Then the CPU outputs signal “AFON2” signal from pin 15 to the AF power amplifier controller (Q51, Q52, D65), according to the “NOIS” signal level. The AF power amplifier controller toggles AF power amplifier (IC21) ON and OFF according to the “AFON” signal.

<TONE SQUELCH>

The tone squelch circuit detects tone signals and opens the squelch only when receiving a signal containing a matched sub audible tone. When the tone squelch is in use, and a signal with a mismatched or no sub audible tone is received, the tone squelch circuit mutes the AF signals even when the noise squelch is open.

• CTCSS/DTCS

A portion of the demodulated AF signals are passed through the active LPF (Q4, R45, R46, R47, R63, R64, C45, C46, C47, C71) to filters CTCSS/DTCS signal. The filtered signal is applied to the CPU (IC14, pin 64). The CPU compares the applied signal and the set CTCSS/DTCS, then outputs control signal as same as “NOISE SQUELCH.”

• 2/5 TONE AND DTMF

2/5 tone signals in the demodulated AF signals are passed through the LPF in the base band IC (IC2) and output from pin 21, then applied to the CPU (IC14, pin 63) via tone amplifier (IC1, pins 8, 9), and decoded.

• BASE BAND IC BLOCK DIAGRAM

5-2 TRANSMITTER CIRCUITS

MICROPHONE AMPLIFIER CIRCUITS

The AF signals from the microphone (MIC signals) are filtered and level-adjusted at the microphone amplifier circuits.

AF signals from the connected microphone (MIC signals) are passed through (bypassed) the ALC (Automatic Level Control) amplifier (FRONT UNIT; IC505, pins 3, 5) via AF switch (FRONT UNIT; IC507, pins 1, 6/7), then applied to the microphone amplifier (FRONT UNIT; IC508, pin 3). The amplified MIC signals are output from pin 4, and applied to the MAIN UNIT.

The MIC signals from the FRONT UNIT are passed through the Int./Ext. MIC switch (IC23, pins 1, 6), and applied to the base band IC (IC2, pin 3) and processed.

The applied MIC signals are amplified at the amplifier (TXA1), and level adjusted at the volume controller (VR1). The level adjusted MIC signals are applied (bypassed) the compressor section, pre-emphasis section, TX/RX HPF, de-scrambler, limiter, splatter, in sequence, then applied to another volume controller.

The compressor compresses the MIC signals to provide high S/N ratio for receive side, and the pre-emphasis obtains +6 dB/oct audio characteristics. The TX/RX HPF filters out 250 Hz and lower audio signals, the limiter limits its level and the splatter filters out 3 kHz and higher audio signals. The filtered MIC signals are level adjusted at another volume controller (VR2), and then output from pin 7 via smoothing filter (SMF).

The MIC signals from the base band IC are passed through the digital/analog switch (IC8, pins 12, 14), FM/PM switch (IC3, pins 13, 14), and applied to the AF mixer (IC1, pin 13) where the MIC signals and tone signals are mixed with. The mixed MIC signals are passed through D/A converter (IC6, pins 3, 4) for level adjustment. The level adjusted MIC signals are then applied to the VCO as modulation signals.

MODULATION CIRCUITS

The modulation circuits modulates the VCO oscillating signal using the modulation signals.

The MIC signals from the microphone amplifier circuits are applied to the D20 of TX VCO (Q19, D14, D17, D18, D20) as the modulation signals, and modulate the VCO oscillating signal by changing the reactance of D20.

The FM-modulated VCO output is amplified by buffer-amplifiers (Q22, Q29), then applied to the power amplifiers via D24 as the TX signal.

SIGNALING ENCODE

5/2-TONE, DTMF and CTCSS/DTCS signals are output from the CPU (IC14) and passed through the LPF (IC7) and level converter (IC6), then applied to the AF mixer (IC1, pin 13) and mixed with MIC signals. The mixed tone signals are passed through the D/A converter (IC6, pins 3, 4) for level adjustment. The level adjusted tone signals are applied to the both of TX VCO (Q19, D14, D17, D18, D20) and reference frequency oscillator (X1, pin 1) via the level adjuster (IC1, pins 1, 3).

TX POWER AMPLIFIERS

The transmit signal from the TX VCO is amplified to the transmit output level by the transmit amplifiers.

The TX VCO output signal from buffer amplifier (Q29) is applied to the YGR amplifiers (Q30, Q53) via the TX/RX switch (D24). The amplified TX signal is passed through the LPF (L29, L30, C269–C271, C290), and applied to the RF power module (IC15, pin 1) and power-amplified to obtain 50 W/25 W (max.) of TX output power.

The power-amplified TX signal is passed through the LPF as a harmonic filter (L33, C305–C308), the antenna switching circuit (D38, D39) and LPF (L38, L39, L45, C343, C345, C349, C350, C356, C357).

The TX signal is also gone through the power detector (D47, D49, D51) and LPF (L40, C369, C370) before being applied to the antenna connector.

• APC CIRCUIT

APC CIRCUIT

The APC (Automatic Power Control) circuit prevents the transition of the transmit output power level which is caused by load mismatching or heat effect, etc. At the power detector, a portion of the transmit signal is rectified to produce DC voltage which is in proportion of the transmit power level.

The rectified voltage is applied to the inverted input terminal of the operational amplifier (IC17, pin 3). The TX power setting voltage "T2" from the D/A converter (IC12, pin 2) is applied to the non-inverted input terminal as the reference.

The operational amplifier compares the rectified voltage and reference voltage "T2," and the difference of the voltage is output from the operational amplifier pin 4, and the output voltage controls the bias of YGR amplifiers (Q30, Q53) and power module (IC15) for stable transmit output power.

5-3 FREQUENCY SYNTHESIZER CIRCUITS

VCO is a oscillator whose oscillating frequency is controlled by adding voltage (lock voltage).

• RX VCO1 (Q18, D10, D13)

RX VCO1 generates the 1st LO signal for receiving 485 MHz and below signals.

• RX VCO2 (Q17, D8, D9)

RX VCO2 generates the 1st LO signal for receiving 485 MHz and above signals.

Each output signals are amplified by the buffer amplifiers (Q22, Q29), and applied to the 1st mixer (IC10, pins 4, 5) via TX/RX switch (D25 is ON, D24 is OFF) and LPF (L22, L23, C215, C216, C236, C237), to be mixed with the received signals to produce the 46.35 MHz 1st IF signal.

• TX VCO (Q19, D14, D17, D18, D20)

The output signal is applied to the transmit amplifiers via the buffer amplifiers (Q22, Q29) and TX/RX switch (D24 is ON, D25 is OFF).

A portion of the buffer-amplified VCO output signals from the buffer amplifier (Q22) are applied to the PLL IC (IC4, pin 6) via doubler (Q25) and BPF (Q5, D4, D5, L4, R77, C84–C90).

• PLL CIRCUITS

PLL IC

The PLL circuit provides stable oscillation of the transmit frequency and receive 1st LO frequency. The PLL output frequency is controlled by the divided ratio (N-data) from the CPU.

The applied signals are divided at the prescaler and programmable counter according to the control signals ("SSO," "PLST" and "SCK") from the CPU. The divided signal is phase-compared with the reference frequency signal from the reference frequency oscillator (X1, pin 3), at the phase detector.

The phase difference is output from pin 4 as a pulse type signal after being passed through the internal charge pump. The output signal is converted into the DC voltage (lock voltage) by passing through the loop filter (Q8, Q9). The lock voltage is applied to the variable capacitors (D10 and D13 of RX VCO1, D8 and D9 of RX VCO2, D14 and D17 of TX VCO), and locked to keep the VCO frequency constant.

If the oscillated signal drifts, its phase changes from that of the reference frequency, causing a lock voltage change to compensate for the drift in the VCO oscillating frequency.

Voltage from the attached battery pack is routed to whole of the circuit in the transceiver via switches and regulators.

Microsoft and Windows are registered trademarks of Microsoft Corporation in the U.S.A. and other countries.

■ BEFORE STARTING SOFTWARE ADJUSTMENT

Clone the adjustment frequencies and settings into the transceiver, and set the configuration using the CS-F5060 CLONING SOFTWARE before starting the software adjustment. Otherwise, the software adjustment can not be started.

CAUTION!: **BACK UP** the originally programmed memory data in the transceiver before programming the adjustment frequencies. When program the adjustment frequencies into the transceiver, the transceiver’s memory data will be overwritten and lose original memory data at the same time.
